Lead Oxides.—Five oxides of lead are known, namely, the suboxide (Pb_2O), the monoxide (PbO), the sesquioxide (Pb_2O_3), the red oxide (Pb_2O_4), and the dioxide (PbO_2). Of these, however, only three—the monoxide, the red oxide, and the dioxide—are of any importance. Lead monoxide (PbO), litharge, massicot, is largely used in the arts, and is made by heating molten lead in a shallow reverberatory furnace with free access of air, the litharge as it forms being pushed on one side so as to expose a fresh surface of the metal. The mass thus obtained is ground and separated from intermixed lead. It is then the buff-colored powder known as ground litharge or massicot. When the oxidation takes place above the melting point of the oxide, as in cupellation, the litharge on solidification breaks up into orange-colored scales and is then known as "flake litharge." Litharge melts at about 600° C. to a clear liquid, and at higher temperatures volatilizes. Lead oxide is a powerful base and dissolves in acids forming salts. At high temperatures it combines readily with silica, forming fusible silicates, and therefore has a very corrosive action on crucibles or firebricks which contain silica. An electrolytic process of making red lead and litharge from galena is used at Niagara Falls. When litharge is heated to dull redness with free access of air, oxygen is taken up and the red oxide (Pb_2O_4) red lead is formed. It is manufactured by roasting ground litharge with free access of air for about 24 hours; the operation being carried on till the required tint is obtained on cooling. It is used as a pigment.

Lead Ores.—Until recently only a small quantity of lead was obtained from any other ore than galena (PbS). Galena (q.v.) is found extensively, more or less pure or associated with other ores, in various parts of the United States, in Great Britain, Germany, Spain, and other European countries. The production of lead in the United States has become a very important feature of the world's industries. The

richest ores are found chiefly in the Western States, the carboniferous limestone, bearing both hard and soft ores, which contain silver chloride and cerussite. The output of smelting-works in Colorado, Idaho, Missouri, Montana, Utah, etc., figures largely in the industrial statistics of the country. (See LEAD INDUSTRY, AMERICAN.) At the present time the main supply of lead is obtained from the Rocky Mountain regions, where the ores are argentiferous—as to some extent all galena is—and the lead-silver mines in some of the States mentioned have produced much wealth for their owners. Conde lead is imported into the United States from British Columbia and Mexico. Other minerals associated with galena are anglesite or sulphate of lead, lanarkite, which is a basic sulphate, pyromorphite, or phosphato-chloride of lead, and bournonite, consisting of the sulphides of lead, copper, and antimony. Galena is very heavy and usually can be easily separated from most of the lighter minerals with which it is associated. The heavier minerals, such as barytes, pyrites, and blonde, are not so easily or completely separated. In Great Britain the ore is crushed to pass through about a half-inch sieve, and is dressed to contain over 76 per cent of lead. In other countries the concentration is not so high and sometimes no dressing is resorted to. This is specially the case in districts where the blast-furnace is used for smelting, since finely divided material is unsuited for the blast-furnace.

Metallurgy.—Galena is the principal lead ore employed for the purposes which metallurgy (q.v.) now so widely subserves. The next important ores, the sulphate and the carbonate, are seldom treated except in combination with others. The three main processes are the air-reduction, the roasting and carbon reduction, and the ion or precipitation reduction processes. Galena when taken from the mine is broken up into small pieces or reduced to powder, and the impurities, in so far as these can be removed mechanically, separated by machines. If the dressed galena is nearly pure, as it often is, the smelting operation is simple. The processes of lead-smelting—galena being the ore—which have grown up in various parts of the world, are strikingly similar in principle, though differing much in detail. In the United States lead is smelted in reverberatory furnaces made of brick, or in water-jacketed blast-furnaces. The blast-furnace is always preferable to the reverberatory where it can be used, and has now become almost universal for lead-smelting.

Compounds of Lead.—One of the most important lead compounds is plumbic carbonate (carbonate of lead, white lead). $PbCO_3$ —the cerussite of mineralogists, and now largely mined in the United States as an ore of lead. White lead is manufactured on a large scale, and is extensively used in the arts as a white pigment and as a body for other colors in paints. (See PAINT.) Another leading compound is plumbic chloride (chloride of lead). $PbCl_2$. The minerals matlockite and mendipite are both oxychlorides of lead. A basic chloride of lead is made for use as a white pigment, which is, however, not so serviceable as ordinary white lead. Lead acetate (sugar of lead), $Pb(C_2H_5O_2)_2 \cdot 3H_2O$, is prepared by dissolving massicot in dilute acetic acid. It can be obtained in transparent crystals or in scales by evaporating the

LEAD INDUSTRY

solution. It is soluble in $1\frac{1}{2}$ parts of cold water, and in eight parts of alcohol. Like litharge, it is used in the manufacture of oil-varnishes. Minium or red lead is much used in the manufacture of flint-glass, as a cement, and as a pigment. For glass-making it requires to be made of very pure lead, as a slight trace of copper would impart a color to the glass. Minium is prepared by heating massicot or monoxide of lead to a temperature of 600° F. in iron trays, in an oven, carefully avoiding fusion. More oxygen is thus gradually absorbed; and a bright-red compound is formed which is the red lead of commerce. Orange lead, made from white lead instead of from massicot, is a very pure kind of red lead. Yellow lead, so called sometimes by manufacturers, is a mixture of the oxides of lead and antimony, which is to some extent used to give a yellow color to earthenware, and as a pigment. The so-called black lead (see GRAPHITE), of which pencils, etc., are made, contains no lead.

Lead in Medicine.—Most of the lead compounds used in medical practice are made into external applications for disorders of the system which manifest themselves upon the skin, although some are employed as sedatives, astringents, etc. Lead acetate is an approved internal remedy in typhoid fever, diarrhoea, and other diseases. Of plasters, ointments, and the like, lead carbonate, lead iodide, and lead oleate are familiar constituents.

Lead Poisoning.—The use of lead in the arts is a frequent cause of painful and sometimes fatal effects, from the metal finding its way into the system. The glazing of culinary vessels with lead; the coloring of confectionery with the chromate, chloride, or carbonate of lead; the sweetening of sour wine by litharge or oxide of lead; the drinking of water which has passed through new lead-pipes; and living much in rooms newly painted with lead-colors, all these things may cause exposure to this peril, and often produce lead or saturnine poisoning. But the most frequent and virulent cases occur among painters and persons engaged in white-lead factories. In lead-poisoning the countenance assumes a sallow, earthy hue, the skin becomes dry and harsh, the digestion is deranged and the bowels constipated, and a sweetish metallic taste is felt in the mouth. A specially important sign is the appearance of a blue or violet line along the margin of the gums and teeth, due to the formation of a sulphite of lead. There is sometimes kidney disease, muscular palsy, severe disturbance of the brain, and even epilepsy and some form of insanity. The most noteworthy result of lead-poisoning is lead-colic, or painter's colic.

S. SANFORD,
Engineering and Mining Journal.

Lead Industry, American. • The use of lead antedates written history, and its abundant occurrence in nature and the ease with which it is reduced from its ores, lead archaeologists to infer, even when little mention and few traces are found, that the ancient nations were familiar with its properties. In Egypt lead was used as an alloy for bronze, and in native form for small images and amulets. The Egyptian slingers used it for sling bullets, as did the Persians. Greece and Rome knew lead as well

as we of to-day. Britain and Spain yielded the Romans thousands of tons. Nearly every land on earth found more or less lead within its borders, and the mining of this metal in a small way was almost universal before the discovery of America. Naturally so base a metal as lead was not the objective treasure of the adventurous miners and metallurgists who first struck their picks into American soil. Gold and silver they sought, and if for many years they found little, their search at least developed many mines and regions, as perhaps the too easy discovery of the yellow metal they coveted might not have done. The first American lead discovered was in 1621, near Jamestown, Va. Iron-smelting works had been erected by the London Company, and an expert metallurgist named John Berkeley was put in charge. Berkeley, in addition to his services rendered to the company, did a little prospecting on his own account, which developed the existence of a vein of galena, the commonest ore of lead. He worked this secretly and supplied his neighbors with lead for bullets and other purposes; but cupidity caused him to keep the location of the vein a secret, so that when, a year or two later, he was killed by Indians, his secret died with him. A few years later a friendly Indian disclosed the location of the old mine, and the lead deposits of Virginia have been worked more or less ever since, although the output has never been very great. Lead was also early discovered in Connecticut and Massachusetts, and by the middle of the last century valuable workings were open in New York State. The lead mines of the East, however, have never been of such importance as those of the great central and western regions of the Upper Mississippi and in Missouri, which were early developed by the French. The lead fields of the Galena district, comprising portions of Iowa, Illinois, and Wisconsin, which have been among the most productive in the world, were probably first discovered and worked by an Indian trader named Nicholas Perrot, who explored from the Canadian settlements of the French as far as the river Des Moines during the last of the 17th century. By 1690 the Indians living in the regions about Galena were smelting and selling lead to the French traders. The region about the present city of Dubuque, which was one of the richest lead districts in America, was also first worked by a Frenchman, Julien Dubuque, who settled among and made friends with the Sacs and Foxes in 1774, just prior to the Revolution. The Indians in 1788 granted to Dubuque the mine he had discovered, known as Prairie du Chien, and in 1796 the grant was confirmed by Baron de Carondelet, the French governor-general of Louisiana. Dubuque worked his mines until his death, in 1809, when the Indians reclaimed them from Dubuque's creditors, and held possession until their removal from the district, in 1832, by the United States government. Dubuque's heirs then claimed the property, but the government ejected them; and legal squabbles kept the status of the district in a most uncertain condition until 1847. The mine La Motte, upon the head waters of the St. Francis River, was also discovered by a Frenchman, the famous adventurer and explorer, M. de la Motte-Cadillac, who founded Detroit. La Motte discovered the celebrated Golden Vein

LEAD INDUSTRY

sometime between 1715 and 1719. The lead fields near Potosi, Mo., were discovered about 1720 by Philippe François Renault, and in 1763 the extensive fields known as Mine à Burton were discovered by Francis Burton, who in 1798 granted about one third of his claim to Moses Austin. The latter erected improved furnaces for smelting, sunk the first shaft ever seen in a lead mine in that district, and began the manufacture of shot and sheet-lead.

At the birth of the United States, France and Spain, with their respective territories of Louisiana and Florida, had jurisdiction over nearly all the valuable mining lands of the lead region; and even where the United States had acquired rights, the mining privileges were usually in the hands of the French and Indians, who recognized their value and were slow to part with them. The Indians, in particular, made the rich surface sheets of galena a source of continual profit. Their methods of smelting were crude in the extreme, consisting usually of a small hole dug in the ground and lined with rocks. This was usually located on a side-hill, both for the purpose of getting a strong air-draft, and also in order that a small tunnel connecting with the bottom of the furnace-hole might be dug, through which the molten lead could run off when the galena and fuel were thrown in and fired. Rough pigs, run in a hollow of the earth itself, and weighing about 75 pounds, were usually made by the Indian squaws and taken to the trading-posts for barter. This method of smelting was wasteful, but with the practically unlimited supply it made little difference, and almost any man who found either a pocket of the "float" mineral or a small vein could mine and smelt it roughly himself. As the surface deposits became exhausted, and the miners had to go deeper, while at the same time improved and economical methods of reducing the ore became necessary, more capital was required and the works became more extensive. There is probably no ore that reduces more readily than galena, yet at the same time the volatility of the molten lead permits great loss from careless methods. The composition of the ore, which is a sulphide, is about eighty per cent of lead, with more or less silver, and sometimes nickel, cobalt, or antimony, with about seventeen per cent of sulphur. Simple roasting suffices for its reduction, the sulphur combining at a low temperature with the oxygen of the air, and passing off. This is, in its simplest statement, the process by which lead is extracted from this ore; and either open furnaces with strong draft, or reverberatory furnaces, are used. Unfortunately a considerable quantity of the lead passes off in fumes from the furnace. In remedying this, some of the modern smelting-works have found it profitable to build a very long funnel-pipe, through which the fumes from the furnace are passed before they reach the air. During this passage they are cooled, and a very appreciable quantity of lead in the form of powder is deposited along the pipe.

In 1838 cerussite, or lead carbonate, was found by the American miners to be reducible and a valuable ore. This ore, previously thrown away by the miners, who called it "dry bone," was found in large quantities, and its utilization very greatly increased the annual output during the decade following. Under this stimulus, and the litigation over the more important lead re-

gions having been settled, the output of the mines in the Galena district jumped from 664,530 pounds in 1825 to 54,494,856 pounds in 1845. The decade between 1840 and 1850 witnessed the high-water mark of the lead interests in America up to the time that the Western lead fields were opened. The rich properties of the Mississippi and in Missouri yielded plentifully, and in their eagerness the mine owners allowed themselves to glut the market, so that prices fell and the entire lead industry received a set-back from which it was some years in recovering. The Jasper County lead fields, which have built up the town of Joplin, Mo., were discovered in 1848. Operations were carried on in a small way, but no general attention was attracted to this district until a dozen years later, when in three years 17,500 tons were produced from these mines. Since then the annual output has been as great as 17,765 tons, and in one year (1884), the disastrous one for all lead interests, as little as 2,665 tons. American lead mines held a poor third place among the productive fields of the world, however, until well into the 70's, ranking below England and Spain. But the development of the great Western deposits of argentiferous galena, discovered in 1864, changed all this. This rich region, neglected on account of its inaccessibility to a market, suddenly took on life and activity with the extension of the railroads through the territory. In 1877 the Eureka district was turning out nearly 20,000 tons of lead annually; the Utah lead fields, worked by the Mormons, were producing 15,000 tons annually so early as 1873, and by 1877 the output had increased to 27,000 tons for the year. Colorado was a year later in showing respectable results for her workings, but by 1883 the output of the mines of that State amounted to the tremendous total of 70,557 tons. This marvelous increase was largely due to the cerusite deposits at Leadville, which were first worked in 1878, and from which fully one half of the total lead production of the State was derived. These Western lead ores were, almost without exception, very rich in silver. While silver in small quantities is found in all galena, and has been extracted even from the ores of the Mississippi and Missouri lead regions in quantity ranging from 6 to 20 ounces per ton, it was only in the Western mines that the precious metal was found in quantity sufficient to make the lead a by-product so far as relative values were considered. So little was thought of lead, in fact, that in the earlier days, when transportation was more difficult and expensive, the ore was cuped at the mines, and only the silver brought to market. For this reason the lead output was dependent upon the silver market, but this is beginning to change, so that the production of the American mines has been developed to a point far in excess of the figures of 25 years ago. The year following the development of the Western argentiferous deposits the United States was producing as great a quantity as was England in 1872, when she was the great lead miner of the world. Less than ten years later the annual output of the American mines had reached a figure greater than the combined production of England, Spain, and the United States in 1872, and the increase was steadily maintained.

In the foreign commerce of the nation lead has, within the past five years, come to play a

LEAD INDUSTRY

far more important part than it ever did before. In 1885 the imports of lead and its manufacturers were only \$486,436, and the exports \$123,466. In 1890 the figures had only increased to \$657,658 for the imports and \$182,412 for the exports; but the very next year saw a marvelous advance, which has continued ever since. The importation of silver-bearing ores, containing much lead, has also become an important matter, and until the silver repeal bill was passed, and the "bull" days for that metal ceased, Mexico had a great interest in that direction.

During the years between 1825 and 1899 the production of the lead mines of this country amounted to nearly 5,000,000 tons. The product, as summarized for the same period by the demi-decades, will give, if the previous explanation of causes is borne in mind, the best illustration of conditions, rise, and progress in the lead industry that can be drawn. Up to 1873 lead was almost entirely obtained from the non-argentiferous ores of the Missouri and Mississippi regions; but after 1875 the table specifies the relative quantities from the two grades of ore. The figures given are standard short tons:

PRODUCTION OF LEAD, 1825 TO 1899.

YEAR	Total	Non-Argen-tifero-us Ore	Argentifero-us Ore
1825	1,500
1830	8,000
1835	13,000
1840	17,000
1845	30,000
1850	22,000
1855	15,800
1860	15,600
1865	14,700
1870	17,830
1875	59,640	24,731	34,909
1880	97,825	27,600	70,135
1885	129,412	21,975	107,437
1890	161,754	31,351	130,403
1895	241,882	39,890	201,992
1899	304,392	40,566	263,826

In the production of the 304,392 tons of metallic lead in 1899 the 39 smelting and refining works employed 8,379 men, to whom was paid in wages for the year \$5,088,684. This sum, together with \$144,195,163 paid out for ores, supplies and materials, and other charges incidental to the carrying on of the business, brought the total expenditures for the year above \$150,000.00. The value of product for the census year was \$175,466,304.

Between lead crude, and cast or hammered into some required form, and lead manufactured, chemically changed, and metamorphosed, there is a great break in time. The chief of all the products of lead manufacture is, of course, the carbonate, which was the psmithium of the Greeks, the cerusa of the Romans, and is the white lead of to-day. As a pigment and base for colors it finds its chiefest use, its well-known body and opacity and ready assimilation with linseed-oil, which is the best of all vehicles for coloring-matters, making it the best substance man has yet discovered for this purpose. Other important lead products are litharge, the yellow protoxide; minium or red lead, which is a combination of the protoxide with a peroxide; orange mine or orange mineral, made by heating white lead; and lead acetate or sugar of lead. There are several other forms in which lead combines, but the substances already given are

those of most importance in the arts. In point of antiquity the oxides seem to be older than the white lead, no traces of which are found in the wall-paints of the Egyptians, Hindus, or other ancient peoples; whereas the oxides are found to have been used both for the glazing of pottery and in colors. White lead was first brought into extended use by the Romans; and Rhodes, the manufacturing centre of antiquity, was the place from which the finest was obtained. Roman women used the ceruse as a cosmetic—a use it also found among the Athenian belles; and minium was used as rouge. In these peculiar uses, despite the well-known injurious qualities of lead, the same substances have remained up to a comparatively recent date. White lead was also used by the Romans as a body for their paints, and both it and its manufacture are described by such ancient writers as Theophrastus, about 300 B.C.; Vitruvius, who wrote about 200 years later; and Pliny and Dioscorides, who filled respectively the records of the two succeeding centuries. These writers all agree in stating that white lead was produced by placing sheets of lead in pots with vinegar or wine lees, and allowing them to stand. This fails to account for the presence of the carbon dioxide necessary to the reaction which converts the lead acetate to the carbonate; but it is certain that this substance was present, for the product was unquestionably white lead. During the Dark Ages, and up so far as the 16th century, there was little use for white lead. About the latter date its manufacture was begun in Holland by what is now known as the "Dutch process." This process, however, can scarcely have been original with the Dutch, since Theophilus, a monk who wrote in the 10th century, describes it very exactly, and the Saracens, Italians, and Spaniards are all said to have used it. With the addition of stable litter banked around the jars, in which small bits of marble are also placed, the Dutch process differs in no way from that described by Pliny, who says: "The lead is thrown into jars filled with vinegar, which are kept closed for ten days; the sort of mold which forms upon the surface is then scraped off, and the lead is again put into the vinegar until the whole of the metal is consumed." The Dutch process has been the one which has proved the best and most profitable. Holland became skilled in this manufacture, and it was also widely used in England. America, on the other hand, had not one establishment for the manufacture of white lead at the close of the 18th century, what white lead was used coming from England; but the primitive habits of the community in those early days caused paint to be regarded not only as a luxury, but, furthermore, as a useless one, since timber was far too plentiful and cheap to require preservation at the expense of paint. After the Revolution more luxurious customs came in, and the use of paint became general in the cities. For the body of this paint all the white lead had to be imported from England. The English product at this time was heavily adulterated, and prices were more than high. So great did the demand become, and so profitable the business to the English manufacturers, that when the manufacture of white lead was proposed and commenced in the United States, the most desperate attempt was made to ruin the new American industry. Had it not been for

LEAD INDUSTRY

the War of 1812 and the consequent shutting out of British goods, it is highly probable that the white lead industry would have been delayed for many years in this hemisphere. The original manufacturer of white lead in the United States was Samuel Wetherill, of Philadelphia, who began the manufacture of white lead early in the 19th century, probably about 1804. A night or two after the factory opened, it was destroyed by fire. About 1809 the factory was rebuilt, and then began the bitterest struggle any two great commercial interests here and in England ever waged. British lead was put on the market at a price that was absolutely impossible for the American maker to quote. The War of 1812 saved Wetherill from ruin, and under the impetus thus given the industry grew rapidly for a few years, its growth being still further aided by the development of the recently acquired lead regions that Louisiana included. By the census of 1810, Wetherill's factory, the only one in the country, was credited with an annual product of 369 tons. Red lead was also produced in small quantities, but the imports of these two products exceeded the domestic production as two and one half to one. In Philadelphia, where the industry began, the second factory in the country was started by John Harrison, at the Kensington works, about 1810. In the latter year the manufacture of white lead was begun at Pittsburgh by Adam Bielin and J. J. Stevenson. Meantime an Englishman named Smith appeared in Philadelphia as a manufacturer of white lead, and all five of these firms were struggling against the English manufacturer when the War of 1812 came to their relief. All these early manufacturers employed, so far as can be learned, the Dutch process. Certain patents for improvements upon it were taken; but the burning of the Patent Office has destroyed all record of them, except that Samuel Wetherill devised and secured a new and better method "for setting the beds or stacks." Stable litter as the source of the required heat was in universal use. In 1814, Welch & Evans, of Philadelphia, patented a method by which granulated lead, placed in revolving lead-lined barrels partly filled with water, was ground by attrition, oxidized by the air, and carbonized by the addition of burning charcoal. A factory for the manufacture of lead by this process was built soon after by a Mr. Richards, who had succeeded the Englishman Smith, but the venture proved unprofitable. The price of white lead before the War of 1812 was 10 to 20 cents a pound. American manufacturers mainly used the imported pig-lead, and the domestic supply was small. When the importation of the foreign pig-lead was suspended by the war, the price of the native metal took a great jump. A great scarcity of the metal resulted, and the price of white lead advanced to 30 cents a pound. This profit, together with the general resumption of business that came after peace was declared, gave a fresh impetus to the white lead industry. Many new works were established, and older ones extended, so that by 1830 there were 12 establishments in the country, of which 8 were east of the Alleghanies. These factories were not turning out over 3,000 tons annually, and as the price of white lead, following a temporary glut of the pig-lead market, had declined to 9 cents per pound, the total value of the year's output was but a little over \$500,000. About two

years after this Augustus Graham, a prominent New York manufacturer of white lead, discovered, by obtaining employment as a common workman in one of the great English factories, the secret of the use of spent tan-bark instead of stable litter as a means of obtaining heat and carbonization. This knowledge worked a considerable change in white lead manufacture, and by 1840 the annual product had increased about two thirds in the whole country. Prices, however, had advanced little, white lead being quoted at only a cent a pound more than in 1830. The sudden bursting forth into prosperity and productivity of the mines in the Galena and Missouri lead regions, during the fifth decade, had an immediate effect upon the white lead industry. The supply was unlimited, but the question of transportation was a serious one. Waterways were the only freight routes available, and Europe was far nearer to the Eastern cities than those towns situated to the westward of the great bar of the Alleghanies. From the Missouri lead fields, and the Galena region as well, the pig-metal was boated down to New Orleans, and there transshipped by vessel to New York. It was a long journey, and a costly one; and in some sections, not readily within the distributive field of New York or the large coast cities, other means were adopted. Sometimes it was carried in prairie schooners from the mines to Milwaukee, where the lead was shipped in sailing vessels to Buffalo. The years 1850 to 1865 marked no important advance in the lead industry. The introduction of the manufactured zinc oxide as a substitute for white lead, together with the advance in the price of metallic lead under the strong influence of the war-time demand, checked the use of the manufactured product until the return of better times at the conclusion of the war. Furthermore, adulteration, which had long been regarded as permissible by white lead makers, came to the condemnation it deserved, and the purer product developed by this sentiment had its immediate effect in raising the manufactured lead in the public estimation. "Sublimed lead" came to be introduced for use as a substitute for white lead. Its discovery resulted from certain unsuccessful experiments made by Lewis and Bartlett to discover an improved and speedier process for manufacturing white lead. On the whole there has been no improvement on the Dutch method.

The lead oxides, of which a considerable quantity is annually produced in the United States, were, like white lead, first manufactured in the western hemisphere at Philadelphia, where, before the War of 1812, there were at least three establishments. Their manufacture has changed little during 200 years. In making red lead, which is, perhaps, the most important of the oxides, the method is simply to heat litharge in a reverberatory furnace, which immediately changes it from yellow to red. In this country this method is the one commonly employed, although some works substitute a bottle-shaped iron cylinder for the reverberatory furnace. Red lead and litharge are usually manufactured at the white lead works, and there are but few separate establishments for the exclusive manufacture of the lead oxides. Orange mineral, a form of lead oxide produced by heating white lead, is another of the useful products of the metal; and the valuable astringent known

LEAD-PENCILS

in medicine as sugar of lead, and chemically as acetate of lead, being obtained by the simple treatment of lead with acetic acid, and without the presence of carbon dioxide, is still another product well known to the commerce of to-day.

The personnel of the white lead industry since its establishment in 1804 has been an interesting one. Outside of those firms already mentioned, only two were established during the second decade, the Cincinnati Manufacturing Company in 1815, and Barney McLennan's works, in the same city, in 1820. Dr. Vandenberg, of Albany, in 1830, together with David Leavitt and John and Augustus Graham, under the title of the Brooklyn White-Lead Works, was operating successfully. Another Brooklyn firm of early establishment was the Union White-Lead Company, started by the Messrs. Cornell about 1827. The Salem Lead Company in 1824, and Francis Peabody in 1826, established the white lead industry in Salem, and Robert McCandless and Richard Conkling established works in Cincinnati during this same decade. During the next decade there were started the Boston Lead Company, in 1831; Great Falls Manufacturing Company, in 1832; Jewett Sons & Company, at Saugerties, in 1838; Gregg & Hagner, at Pittsburg, in 1837; and Reed & Hoffman, at St. Louis, in 1837. This last establishment afterward became the Collier White-Lead and Oil Company. From 1840 to 1850 was a period of rapid growth. Among the larger works established were the Atlantic White-Lead Company, of New York, founded by Mr. Robert Colgate; John Jewett & Sons' Staten Island works; the Great Falls Manufacturing Company, changed by Batelle & Renwick to the Ulster White-Lead Company; Suffolk Lead Works and Norfolk Lead Company, of Boston; the Forest River Lead Company, of Salem, successors to Francis Peabody; Thompson & Company, of Buffalo; B. A. Farnestock & Company, of Pittsburg; Eagle White-Lead Works, at Cincinnati; and William Glasgow, Jr.'s, works, at St. Louis.

The succeeding decade saw less increase. William Wood and T. J. McCoy took the Eagle Works, of Cincinnati; the Niagara White-Lead Company started at Buffalo, and Wilson, Waters & Company at Louisville. This was but a lull, however, that was to give place to renewed activity. From 1860 to 1870 there were founded such great establishments as the St. Louis Lead and Oil Company, which succeeded the O'Fallon White-Lead and Oil Company in 1865; the Southern White-Lead Company, established by Platt & Thornburg in the same year; Goshorn Brothers, who secured the McCandless establishment in Cincinnati, and afterward organized it as the Anchor White-Lead Company; the Eagle White-Lead Company, also of Cincinnati; the Shipman White-Lead Company, organized at Chicago by D. B. Shipman; J. H. Morley's works at Cleveland; Haslett, Leonard & Company, who succeeded Waters in Louisville; Lewis & Schoonmaker, of Louisville, who later sold out to T. J. McCoy and the American White-Lead Company; the Western White-Lead Company, in Philadelphia; the Cornell Lead Company, which succeeded the Niagara Company, at Buffalo; Hall, Bradley & Company, of New York and Brooklyn; the Salem Lead Company, a new company organized by Mr. Francis Brown at Salem; and the Maryland

White-Lead Company, which was established in Baltimore in 1867. Since this period the have been comparatively few large establishments founded. Even in 1870 the tendency toward consolidation was noticeable, and the two largest plants founded during the succeeding decade were absorbed by older companies.

The manufacture of white lead in former years had been very profitable. Such severe competition was the result that many factories became unprofitable. In order to lessen this competition various devices of association were successively tried, and in 1889 H. H. Roger and the late Charles M. Pratt, who both had large experience in the lead and paint business, attempted an organization patterned after the Standard Oil Company. After a period of ill-success arrangements were made by which other great factories of the country, the John T. Lewis & Brothers Company, Philadelphia, the Salem Company, of Boston, the Atlantic Company, of Brooklyn, and the Collier and Southern Companies, of St. Louis, were acquired. The writer then became president, and acquired the important works of Armstrong, McElvay & Company and the Davis-Chambers Company, a Pittsburg. By the end of that year the National Lead Trust manufactured 80 per cent of the country's production of white lead, 70 per cent of red lead, 15 per cent of linseed-oil, 10 per cent of sheet-lead, 9 per cent of lead pipe, and 60 per cent of lead acetate, together with sundry other of the important manufactures of lead. Many small factories operating in a desultory way, with frequent stoppages, were closed for good; works in favorable localities, and capable of producing the best results in any one direction, were devoted to this branch, enlarged and improved, and the best class of employees selected and taken to the more important works. New machinery and more healthful appliance were at once put into use. Schools for mutual education among the more important manufacturers were organized, and the expert knowledge of each placed at the service of all. Efforts to reduce the unwieldy capitalization culminated successfully in 1891, when the Lead Trust was dissolved, and a new company, organized under the laws of the State of New Jersey, with a capital of \$15,000,000 preferred and \$15,000,000 common stock, took its place. The National Lead Company enjoys the unique position of never having borrowed a dollar. Every department is well managed, and the character of all manufactured products marvelously improved and placed upon the market at prices lower than ever before known.

W. P. THOMPSON,
President National Lead Company.

Lead-pencils. Lead-pencil manufacture in the United States did not begin until 1860, but in 1903 there is estimated to be \$4,000,000 capital invested in the industry, and American lead-pencils are sold all over the world. This country is particularly adapted to the production, for it has rich graphite mines, and extraordinary facilities, also, for obtaining this substance from elsewhere; it also has the only great forests of cedar in the world, from which the stock of the pencil is made, and even sends quantities of cedar to foreign pencil makers. Above all, it has had numbers of ingenious mechanics to originate labor-saving machinery. Germany is

LEAD-POISONING—LEAF-HOPPER

the pioneer country in lead-pencil manufacture, and from that nation came many of the founders of the industry in the United States. Among the first in this country were Eberhard Faber, Joseph Reckendorfer, and Henry Baulzheimer. New York city and vicinity have always been the seat of lead-pencil manufacture in this country, and among the prominent manufacturing firms now located there are the American Lead-Pencil Company, the Eagle Pencil Company, and the works and office of Eberhard Faber; while in Jersey City is the plant of the Joseph Dixon Crucible Company, founded by Joseph Dixon at Salem, Mass., as early as 1826, and moved to Jersey City in 1840. The company did not begin to make lead-pencils until 1872. It is the pioneer graphite company in the United States, if not in the world. The plumbago crucibles (which are identical with graphite) were invented by Joseph Dixon. Graphite now enters largely into every department of the mechanical arts. The American output of pencils is calculated to be 5,000 gross daily. American lead-pencils now supply nearly all the home demand and are sold everywhere. Many novelties in pencils have originated in the United States.

Lead-poisoning. See LEAD.

Leading Star. See LODESTAR.

Leadville, led'vil, Colo., a city and the county-seat of Lake County, 80 miles by rail southwest of Denver, the State capital, on the Colorado M., Colorado & S., and the Denver & R. G. R.R.'s. It is situated 10,200 feet above the sea amid picturesque scenery, near the headwaters of the Arkansas River in central Colorado, between the Mosquito and Sawatch ranges of the Rocky Mountains. Leadville was first settled in 1860 by miners and prospectors, but after a period of comparative prosperity as a gold-mining centre declined with the exhaustion of the first discovered deposits. It revived with the discovery of 1877 of rich lead and silver deposits, followed by the discovery of other gold, zinc, copper, bismuth, and manganese deposits, and is now one of the most important localities in the world for the mining and reduction of the ores of the precious metals, some of the mines being 700 feet deep. Leadville's annual production of metals amounts to \$10,000,000. It is the mining, farming, and grazing trade centre of an extensive region, has fine buildings, including a Carnegie library, opera house, theatre, court-house, jail, hospital, and almshouse, has a parochial school, a high school and four grade schools, two Roman Catholic churches, two Methodist, two Presbyterian, a Baptist, a Congregational, and a Lutheran, is lighted by gas and electricity, has an excellent water supply, and well organized fire and police departments. Besides its large sampling, refining and reduction works, smelting furnaces, etc., its mines employing 4,000 workmen, its smelting 1,200, and incidental to mining and smelting 1,200; it has also iron foundries, manufactures of machinery, ice, jewelry and novelties, and a government fish-hatchery. There are two National banks, the volume of business of the Carbonate National bank in 1902-3 being, receipts \$24,071,492 and disbursements \$24,095,624. The city is administered by a mayor and common council of six members elected biennially. The population,

consisting of Americans, Irish, Swedes, Finns, Austrians, Italians, Germans, Cornish, and English, was (1890) 10,384; (1900) 12,455.

HENRY C. BULLER,
Editor of 'Herald Democrat.'

Leaf-beetle, a popular name for many members of the family *Chrysomelidae* (q.v.), which embraces about 18,000 widely distributed species, about 600 of which are found in North America. The larvæ, which feed upon the succulent parts, either fully exposed, in protective cases, beneath the epidermis as leaf-miners or stalk-borers, are all soft-bodied six-footed creatures with great appetites. Some larvae feed on roots, some are aquatic, and many cover themselves with excrement as a protection against their enemies. The adults of several tropical species are of such brilliant colors as to be used for jewelry when mounted in gold settings. The family includes many species considered serious pests of cultivated plants. Some of the most noted of these are the flea-beetles, tortoise-beetles, potato and asparagus beetles, elm-leaf beetle and the diabroticas, represented by the striped, and the spotted cucumber-beetle. These are treated under their food-plant titles.

Leaf-bug, or Plant-bug, bugs of the family *Capsidae*, which suck the juices of plants. Two hundred and fifty of the thousand or more species described occur in the United States, and all except the predaceous species are vegetable feeders, a few being considered pests. They are generally oval or elongated, yellowish or greenish, sometimes with lines or dots of red or black. All have a decidedly "buggy" odor. Among the best known species are the red-bug or cotton-stainer (*Dysdercus suturellus*), so called because its excrement stains the cotton in the opening boll, thus reducing the grade. It is less troublesome than formerly because the piles of cottonseed in which it used to breed are now used for oil instead of being thrown in heaps to decay. The insect also attacks oranges in Florida. Cottonseed will attract them away from the trees. Another species troublesome on currants, gooseberries, dahlias, etc., is the four-lined leaf-bug (*Paciocapsus lineatus*). Its eggs are laid in the young twigs which may be cut in autumn or winter and burned. The insects may also be jarred off the plants into receptacles while sluggish in the early morning.

Leaf-cutter Bee, one of the large bees of the genus *Megachile*, of which a common species in the United States is *M. cetrularis*. It is a "thick-bodied bee with a large square head, stout scissors-like jaws, and with a thick mass of dense hairs on the under side of the tail for the purpose of carrying pollen." These bees make their nests in the hollow stems of elder-bushes, or, nowadays, often in crevices about buildings, and form their cells of round pieces which they cut out of tender leaves of many sorts of trees and bushes, especially the rose. Many cells are made, each containing an egg and store of pollen, and the whole economy of the group is very interesting. There are many species in various parts of the world. Consult: Packard, 'Guide to the Study of Insects' (1889).

Leaf-cutting Ants. See ANTS.

Leaf-hopper, any member of the family *Jassidae*, which includes a very large number of small bugs greatly varying in form and often

LEAF-INSECT — LEAGUE

grotesque. They are especially numerous in grass and grain, which they are believed to injure to a greater extent than is usually supposed. Among the best-known species is the grape-vine leaf-hopper (*Erythroneura vitis*), which is often so abundant in vineyards that the leaves may turn brown from the insects' punctures. They have been effectively caught by tapping the vines to make the insects jump against a screen smeared with tar or a fan similarly covered and kept in constant motion close to the vines. This species is sometimes erroneously called "thrips" (q.v.). Among the best known of the grass-feeding host of species is the destructive leaf-hopper (*Cicadula* or *Limotettix exitosa*). This is sometimes caught in wide pans covered with tar and dragged across the field.

Leaf-insect, or Walking Leaf, tropical species of the family *Phasmidae*, which is represented in temperate climates by the walking-stick (q.v.). They are so called because of the remarkable resemblance of their wings to leaves, not only in color but also in the arrangement of the veins, etc., so that the natives believe that the insects are really leaves which have acquired organs of locomotion, digestion, etc. Their legs also look more or less like twigs, and their eggs, which are dropped upon the ground from the foliage where the insects feed, look very much like seeds. This likeness is of use as a protection from enemies. See MIMICRY.

Leaf-miner, any insect of the superfamily *Tineoidea*, which comprises several families of very small moths, most of whose larvæ feed upon the soft tissues (parenchyma) of leaves and green stems beneath the epidermis, sometimes eating away rounded passages and sometimes long serpentine paths. More than 4,000 species have been described, of which fully 1,000 are American. The adults are often remarkably beautiful, exhibiting under the microscope a covering of lustrous scales. Among the plants that these insects attack injuriously are oaks, pines, maples, and palmettos. Some of the leaf-feeding species have developed the habit of feeding during their later larval days upon the outside of the leaf, either fully exposed or in a protective case. Others have assumed root- and seed-feeding habits; still others have become twig-borers, and gall-formers. Some of the related species live upon animal skins, fur, wool, etc. (See CLOTHES-MOTH.) A few flies of the families *Anthomyiidae* and *Oscinidae* are leaf-miners, as are also some leaf-beetles of the family *Hispini* and some sawflies of the family *Tenthredinidae*. Consult: Comstock, 'Manual for the Study of Insects' (1895); Sharp, 'Cambridge Natural History,' Vol. VI. (1899).

Leaf-monkey, an Anglo-Indian name for a langur (q.v.).

Leaf-nosed Bats, a general term for such bats as have on the snout upright leaf-like growths of highly sensitive membrane which is presumably of great assistance to them in making their way about in darkness, and in finding and taking their insect-prey. (See BAT.) These folds of skin are, naturally enough, called the nose-leaf, and may be comparatively small and simple, or so large as to form a grotesque mask, such as gives so extraordinary appearance to the horse-shoe and other leaf-nosed bats of the fam-

ily *Rhinolophidae*, and to the "false vampires" of the family *Nycteridae*. North American bats show very little of this peculiarity. These complicated membranes are always fringed with long fine hairs, which serve the purpose of the tactile whiskers of cats; and the bats possessing this feature are more thoroughly nocturnal than those in which it is lacking or little developed.

Leaf-roller, Leaf-tyer, or Leaf-sewer, a small moth, in most cases one of the family *Tortricidae*, whose caterpillar rolls a leaf or a part of a leaf into a case, tying it into a cylindrical case with silken bands and lining this case with silk, so as to form a sort of cocoon in which it may transform safely into the pupa stage. In some cases the nest is formed by fastening together several leaves. "In most cases," says Comstock, "the building of the nest is the work of a single larva, but in very many instances several larvæ work to build a common nest." Each species makes its nest of a particular form, and infests some special kind of plant or tree; and many do considerable injury, especially among greenhouse plants and orchard trees.

Leaf-tyer. See LEAF-ROLLER.

League, lēg, a measure of length varying in different countries. The word is supposed to be of Celtic origin, but it has been introduced into the modern languages of Latin origin through the Latin *leuca*. The Roman league was equal to 1,500 paces, each of 5 feet. The English land league is 3 statute miles, and the nautical league 3 equatorial miles, or 3.457875 statute miles. The Italian league is reckoned as equal to 4 miles, each of 5,000 feet. The Spanish league varies very much according to the locality. On the modern Spanish roads the league is estimated at 8,000 *varas*, or 7,416 English yards. The Portuguese league is equal to 3.84 English miles. In the old French measures the length of the league was different in every district, but the three principal leagues were the legal or posting league, equal to rather less than 2½ English miles, the marine league somewhat more than 3½ English miles, and the astronomical league equal to about 2¾ English miles. The metric league is reckoned as equal to 4 kilomètres.

League, political connections which have been called *alliances* since the French language has become the diplomatic language of Europe. Among these are the League of Cambrai, formed in 1508 between Louis XII., king of France, the German emperor Maximilian, and Ferdinand of Spain, for the purpose of humbling the Republic of Venice, and which was joined in 1509 by Pope Julius II. This league was dissolved in 1510, as many similar ones have been, in consequence of mutual distrust, and was succeeded by the *liga santa*, or holy league, between the pope, Maximilian, Ferdinand, and Venice. The object of this was to compel Louis XII., whose allies had now become his enemies, to renounce his conquests in Italy; which object was gained. Thirty years afterward a holy league was formed in Germany. When the principal Protestant princes in Germany united in 1530, and again in greater numbers in 1536, to form the union of Schmalkalden, in order to protect their common faith and withstand the Emperor Charles V., the Roman Catholic princes assembled at Nuremberg, in 1538, to take measures for the sup-

LEAHY—LEASE

port of their own faith, and to oppose the designs of the Protestant princes; and as their league had the protection of the Roman Catholic Church for its object, they termed it the *holy league*. A fourth league was headed by Henry, duke of Guise, in 1576, against Henry III. of France. Its ostensible object was the support of the Roman Catholic religion. There was a fifth league in Germany in the 17th century.

Leahy, lē'hi, William Augustine, American author: b. Boston 18 July 1867. He was graduated from Harvard in 1888, was literary editor of the Boston *Traveller* in 1893–4, then entered general literary work, and contributed verse and short stories to magazines. In 1902 he was appointed secretary to the music department of Boston. His works are: 'The Siege of Syracuse' (1889); 'The Incendiary' (1896), which obtained a prize offered by the Chicago *Record*; and a 'History of the Catholic Church in New England' (1899).

Leake, lēk, William Martin, English archaeologist and topographer: b. London 14 Jan. 1777; d. Brighton 6 Jan. 1860. An officer in the West-Indian service (1794–8), and artillery instructor at Constantinople in early life, he later traveled in the East, and was engaged in surveys and diplomatic business for the British government in Greece (1805–9). Among his publications are: 'Researches in Greece' (1814); 'Topography of Athens' (1821: 2d ed. 1841), a learned and still valuable work; 'Historical Outline of the Greek Revolution' (1826); 'Travels in Northern Greece' (1835); 'Peloponnesia' (1840). Consult: Marsden, 'Brief Memoir of the Life and Writings of W. M. Leake' (1864).

Lean'der and Hero. See HERO.

Leaning Tower. See PISA.

Leap Year, the name given in Great Britain to every year of 366 days. The length of the year is a little less than 365½ days. Julius Cæsar, in reforming the calendar, arranged that in every fourth year February should have 29 days instead of 28, and that two days should be called by the same name. The day whose name was repeated was, according to the Roman method of reckoning, the sixth before the calends of March, that is, the 24th February, and the year in which this name was given to two successive days was named *bisextile* (*bis*, twice; *sextus*, sixth). The name leap year is perhaps due to the notion that the calendar takes a leap of one day every fourth year to make up for its ordinary year being one fourth day too short. Every year is a leap year which is divisible by four without remainder, except the concluding years of centuries, every fourth only of which is a leap year; thus the years 1800 and 1900 are not leap years, but 2000 and 2400 are.

Lear, lēr, Edward, English author and artist: b. London 12 May 1812; d. San Remo 29 Jan. 1888. In 1831 he became draftsman to the London Zoological Society. His illustrations of the 'Family of the Psittacidae' (1832) was followed by many other illustrations for zoological works by Gould, Bell, Swainson, Jardine, and Gray. In 1837 he visited Italy and the East, and in those parts spent most of his remaining days, chiefly occupied with landscape painting. He exhibited 'Dead Birds' in 1836, and in 1850 was represented at the Royal Academy exhibi-

tion by 'Claude Lorraine's House on the Tiber.' As an author he is best known by his 'Book of Nonsense' (1846); 'Nonsense Songs and Stories' (1871); 'More Nonsense Songs,' etc. (1872); and 'Laughable Lyrics' (1877). He also wrote 'Views in Rome and its Environs' (1841); 'Illustrated Excursions in Italy' (1846); 'Journal of a Landscape Painter in Greece and Albania' (1851); 'Journal of a Landscape Painter in Southern Calabria' (1852); 'Views in the Seven Ionian Islands' (1863); and 'Journal of a Landscape Painter in Corsica' (1870). Tennyson's verses 'To E. L. on his Travels in Greece' were addressed to Lear.

Lear, Tobias, American diplomatist: b. Portsmouth, N. H., about 1760; d. Washington, D. C., 11 Oct. 1826. He was graduated at Harvard in 1783, and in 1785 became private secretary to General Washington, to whose domestic affairs he attended for several years, and by whom, in his will, Lear was most liberally remembered. In 1802 he was consul-general at San Domingo, and afterward consul-general at Algiers and commissioner to conclude a peace with Tripoli. He discharged this last duty in 1805 in a manner which gave offense in certain quarters, but his conduct was approved by the Federal government. He returned shortly after to the United States, and at the time of his death (by suicide), was employed in Washington as accountant of the War Department.

Lear. Shakespeare's great drama of 'King Lear' was written between 1603 and 1606. The bare historical outline of the story of the King he obtained probably from Holinshed or from an old play, the 'Chronicle History of Leir'; the sad story of Gloster was found in Sir Philip Sidney's 'Arcadia.' The motifs of the drama are the wronging of children by parents and of parents by children.

Leary, Richard Phillips, American naval officer: b. Baltimore 3 Nov. 1842; d. Boston 27 Dec. 1901. He was graduated at the United States Naval Academy in 1860; served during the blockade of Charleston 1863–5; promoted commander in 1882. During the Samoan revolution in 1888 he was the senior naval officer present at the critical moment. He was promoted captain in April 1897; commanded the cruiser San Francisco in 1897–8; and when the New Orleans was purchased from Brazil convoyed that vessel to the United States. At the close of the Spanish-American war he was appointed the first American governor of Guam, and served there till relieved, on his own request, in April 1900.

Lease, Mary Elizabeth Clyens, American writer and speaker: b. Ridgway, Pa., 11 Sept. 1853. She was educated at Saint Elizabeth's Academy, Allegany, N. Y., and after graduating there removed to Kansas, where in 1885 she was admitted to the bar. In 1888, at a union labor convention, she made her first political speech, and in the campaign of 1890 delivered over 160 addresses in the interest of the Farmers' Alliance (q.v.) to the triumph of which that year in Kansas her effective efforts were believed to have largely contributed. She was afterward appointed president of the State Board of Charities, being the first woman chosen to such an office in this country. At the Columbian Exposition she was orator on Kansas day; rep-

LEASE — LEATHER

resented Kansas at the National Conference of Charities and Corrections; and was national vice-president of the World's Peace Congress in Chicago, in 1893. She has written much for periodicals; is author of 'The Problem of Civilization Solved'; and has lectured frequently on literary, political, and economic subjects.

Lease, a species of contract granting the possession of lands, tenements, or incorporeal hereditaments, for life or a limited term of years, or during the pleasure of the contracting parties. The grantor is called the lessor and the grantee the lessee. A lease may be in writing or by parol, but the former is more satisfactory, as it usually sets out in regular form and binding terms the respective rights of the contracting parties. A lease contract establishes the relation of landlord and tenant between the lessor and lessee, unless its terms limit the relation of the parties. A lessor who holds an estate for years only may under-lease in such a manner as to establish a technical relation of landlord and tenant between the owner of the fee and the lessee. One of the essential requisites of a lease is, that its duration must be for a shorter period than the duration of the interest of the lessor in the property leased; for if the holder of an interest less than that of a fee leases his interest for the full term of its continuance it would be in effect an assignment or sale of his interest and in no sense a lease. In a lease proper, the lessor reserves to himself a reversionary interest in the property included in the lease. The beginning and termination of which are to be determined by the agreement of the parties. This agreement must also include a designation of the premises, estate or interest, intended to pass to the lessee. A term, however, is perfected only by the entry of the lessee. Even after the making of a lease the estate remains in the lessor up to such time as the lessee actually enters into possession, and the only right the lessee has in the estate is that of making an entry, which must be exercised to give him the additional rights provided for in the lease. All persons possessed of lands or tenements, or interest therein, competent to do business and under no legal disability, as of unsound mind, immature age, or the like, may enter into a lease contract.

Leasehold. A leasehold is an estate held under or by virtue of a lease. An estate for years usually commences by means of a written lease. It is important to distinguish between a lease and an agreement to lease, the former being a completed contract and the latter only a stipulation for the formation of a contract at some future time. It is often difficult to determine to which of the two classes an instrument belongs, without resorting to an interpretation based upon the intentions of the contracting parties. If a lessee fails or refuses to enter into possession under and in accordance with the terms of a lease, the possession remains undisturbed in the lessor, and the remedy of the latter would be by an action for not entering into possession and for consequent damages, rather than for a breach of the conditions of the terms of the lease, the relation of landlord and tenant not having been established before an entry under the lease. A person can convey by lease no greater interest than he possesses in an estate. If the lessor has only a life estate it

terminates with his death, although he may have executed a lease for a term of years not completed at the time of his death. The ordinary powers, duties and obligations of the contracting parties may be increased, diminished, or modified by special provisions in a lease. Many lease contracts provide for all of the contingencies which can ordinarily happen. It is not infrequent that a clause in the instrument provides that the lessee may build upon land leased to him, and that he shall have the right to remove his buildings at the expiration of his term, or purchase the fee. Any provision not illegal or inconsistent with public policy may be an incident of a leasehold.

Leather, Shoe, Manufacture of. The art of manufacturing raw hides into leather has been known for centuries, but only through many changes and improvements did the industry reach the perfect condition it has developed into at the present time. Until a half-century ago the leather turned out was at its best crude, and to-day would not be considered fit to be used. But since the introduction of machinery which simplified the process and reduced the time of tanning to from 90 to 120 days on sole-leather, and incidentally lessened the cost, better leather is being turned out; and each year brings forth some new invention that further perfects the process and reduces the time and expense. Until within about 20 years bark was relied upon as absolutely essential to manufacture good leather, but extracts were introduced which did away with bark in part, and to-day there are tanneries that manufacture leather by quebracho and other extracts entirely. There have been many adverse comments on the extract tanning, but it is the process of the future, and tanners who have no faith in it and predict failure should visit some of the tanneries where extract-tanned leather is made, and see what excellent results are produced in 45 days, or little more than half the time that tanners who do not use this process take to tan their hides into leather.

The chrome process is another great invention that simplified the art, and manufacturers are enabled to turn out better leather at less cost and in much less time than by the old process. The chrome process is now in general use in the manufacture of upper leathers, and with excellent results. It was only a short time since that the chrome tannage came into general use in the manufacture of patent leather for shoe purposes, and to-day it is used extensively, as it gives a better grain and a tougher and more pliable leather than was obtained under the old process. Tanners and chemists have for years been trying to tan leather, both upper and sole, quickly and cheaply, and all sorts of inventions have been tried, with the result that the time has been cut down considerably; and in recent experiments the tanning of leather was accomplished in about 30 days for heavy leather by the use of extract and the drum to tan the hides in—a saving of from 60 to 90 days. This is of great benefit to the tanner; it brings him much nearer the hide-market than when leather was only tanned in three to four months, and he is not compelled to take such long chances on the market.

Leather manufacturers are divided into two great classes; namely, the sole-leather tanners and those that manufacture upper leathers.

LEATHER

Each of these classes is variously subdivided, some making oak sole-leather, some union, and others hemlock. The upper-leather tanners are divided into patent-leather tanners, for shoe purposes, and for carriage and furniture use, glazed-kid tanners — glazed kid being commonly known as "vici kid," from the fact that the first man to use the process whereby good glazed kid was manufactured called his stock "vici" calfskins, etc. There is a difference in the process of tanning these different varieties, and various kinds of hides and skins are used; skins, for example, that are adaptable for the manufacture of glazed kid could not be used to manufacture calfskins; again, hides that are used for patent-leather purposes could not be used with any degree of success in tanning some kinds of sole-leather.

Sole-Leather.— This is made in three different kinds — hemlock, oak, and union. Hemlock sole-leather is divided into acid, non-acid, and slaughter acid. For the acid leather dry foreign and green hides are used, such as Bogotas, etc.; Central American, Orinoco, Buenos Ayres, Chinas, Bufaloes (hides that come from Calcutta), etc. For non-acid leather dry hides only are used. For acid slaughter leather green hides are used.

In the tanning of dry hides, they are first prepared by soaking, then they are milled, re-soaked and sweated, unhaired, and unfleshed. When the hide has reached this stage it is ready to be put through the tanning process, and not before. The reason of this is that dry hides must be brought back to their original condition; that is, the same condition they were in when they were taken off the animal.

In acid leather, when the hide has reached the stage where it is ready for the tan-vats, that is, after it has been unhaired, it is first put into a vat for coloring with a weak tanning liquor, either sweet or sour, sweet giving a deeper grain than sour liquors; tanners use either as preferred. In order to plump it, the hide is then put into sulphuric acid for one day. This acid is about $\frac{1}{4}$ to $\frac{1}{2}$ per cent in strength. The hide is then put through the different layers of liquor in the tannery, beginning with a low degree liquor, and gradually increasing through liquors of greater density, until the hide is tanned through and is now leather. After removal from the last liquor it is washed in a scrub-wheel, in order to remove any liquor that may remain in the hide, and is then bleached. The principal materials used in bleaching are sal-soda and sulphuric acid. From the bleach the leather is piled up for a day, in order to drain out the excess of water, and then given an application of cod or other oils on both the grain and flesh sides. The leather is then hung up in a loft to dry. After drying it is taken down and sprinkled with water upon the grain side, and laid away in boxes over night. The object is to assist in the better preparation of the leather for rolling, which is the next process it goes through. From the boxes the leather is rolled twice the same day, once in the morning and again in the afternoon. From the second rolling it is hung up in a warm loft to dry out perfectly before being shipped out of the tannery, ready for the market. From the time the hide leaves the liquor until finished the process is the same for all classes of sole-leather.

In non-acid hemlock leather the beam-house work is exactly the same as in acid leather until it goes into the coloring mill, they both being made out of dry hides, and the same process must be gone through to prepare them for tanning. When the hide has gone through the beam-house and been unhaired it is put directly into vats of weak liquors, and is plumped by being handled in a series of weak liquors for a period of 10 to 12 days. The rest of the process is the same as in the case of acid leather above. The liquors that the hides are put through in order to be tanned are made from bark and extracts. The principal extracts used are quebracho and hemlock, acid and non-acid leather being made from hemlock-bark and extracts, which give it the rich red color that distinguishes it from other tannages. Tanners use extracts in part (some use them altogether) for tanning, as they are cheaper than bark and produce better work. One ton of solid extract is equal to 10 tons of bark, and the advantages of using extracts are the shortening of the time of tanning, and the production of a better filled and firmer piece of leather, with a far brighter and lighter color.

Hemlock acid slaughter sole-leather is made from green hides. To prepare these for tanning, they are first soaked, then put into limes, and then fleshed. Some tanners reverse this method. Next, the hide is bated, that is, given a bath of lactic or acetic acid, to remove the lime; this is called "bating the hide." The lime softens in this bath and dissolves the cells, so that the hair can be removed either by an unhauling-machine or on the beam by hand. From this part on most tanners plump in sulphuric acid, and carry on the process just as with acid leather. It takes from 90 to 120 days to tan hides into leather.

In making oak sole-leather only green hides are used, Colorado, Texas, and packer hides, etc. There is very little difference in tanning the various kinds of sole-leather, and the same formula that is used in tanning non-acid hemlock leather can be applied to oak sole-leather, with the exception that the hides must be limed, instead of being sweated, to remove the hair. Oak is a light-colored leather, and this color is got by using oak-bark, or oak-bark and extracts combined in the liquors, while the hides are going through the tanning process.

For making union sole-leather the same hides are used as for oak-leather — green hides — and as the name denotes, it is made by a union of hemlock and oak-bark; or in some cases oak-bark is done away with and extracts are substituted, the principal extracts used being chestnut wood and quebracho. The treatment gives a yellowish color by which it is readily distinguished from oak. The manufacturing process is exactly the same as in tanning oak-leather (see above).

Upper Leathers.— There are several different kinds of upper leathers made, but the principal ones are glazed kid, patent-leather, and calfskins. Glazed kid is made from dry goat-skins, which are imported to this country, as but very few goats are raised here for their skins. In those foreign lands from which the greater number of skins come the industry of raising goats is made profitable, since not only is the skin used for tanning purposes, but the

LEATHER

flesh is sold to the inhabitants for food. The skin is first soaked, and then milled, after which it is put into lime, in which it stays for a period of 12 to 14 days. It is then unhaired, principally to save the hair, which is sold, and the skin is put back into the lime. After the skin has been unhaired and properly limed, it is washed and fleshed, then it is pured, that is, the skin is cleaned in order to make it ready for the other process. The skin is now ready to be tanned, and is first given, for a few hours, a bath of bichromate of potash and muriatic acid, after which it is put into a drum overnight, in the same liquors. In the morning the skin is taken out of the drum and is "put-out" by a process of pressing out the liquor and flattening the grain. It is now given a second bath, this time in hyposulphite of soda and muriatic acid, which completes the tanning process.

After the skin has been thoroughly tanned it is washed to get the acid out, and is then "put-out" again before it goes into the drum to receive the stain or coloring matter. When the stain has been put on the skin it receives the fat liquor, which consists of soap and oil. This is done in order to give the skin life, as otherwise it would be too dry, and not strong enough to be useful for the purpose intended. After the skin has received the fat liquor it is pleated (doubled up with the grain out, and slicked to get the water out of the grain, and also to smooth out the grain). The skin is now ready for the coloring process, and is colored by dipping it in a color-box, the color being composed of logwood and copperas. Some tanners also use anilines to give the skin the black color. It is now washed by dipping it in water, and is then "struck-out" on the machine, a process which flattens out the grain and clears the skin of water. The skin is now taken and glycerined, and then oiled, after which it is hung up to dry. After the skin has been thoroughly dried it is kept a few days to season, and is then put into damp sawdust to moisten, as otherwise it could not be properly worked. The skin is then staked by the machine, for stretching and softening the skin, is then dried, and receives a perching, which consists of a light staking again. The skin is now ready to be seasoned, the principal ingredient of the seasoning matter being blood of cows, steers, bulls, etc. The skin is now again dried and ready to receive the first glazing, which is done by machine. After glazing, the skin is seasoned a second time, dried again, and receives a second glazing. It is seasoned for the third time, dried, and receives the finishing glaze. The skin is now ready for the market, and is measured and selected for quality and weight, when it is sold to the shoe manufacturer, who cuts it up into shoe-uppers, etc. The complete tanning process, from the time the skin is put into the first soak until it is ready for the market, takes from three to four weeks.

Another simple process of tanning goatskins of the cheaper variety is the one-bath chrome tannage, which combines low cost with good leather. The skin is first given a very thorough liming, in order to get the grain and fibre as soft as possible. After liming, the skin is bated thoroughly in manure-bait, in order to overcome as much as possible the roughness and coarseness of the grain. The grain is now

thoroughly worked out, and the skin washed and put in pickle. The pickle is composed of salt, sulphuric acid, and water. So much water should be used that the skin can easily be stirred about in the pickle; during the first hour it is stirred continually, after which it may be allowed to rest for several hours with occasional stirrings. From the pickle the skin is then drained and is now ready for tanning.

For each 100 pounds of skins, a solution composed of eight gallons of water and one pound of Glauber's salt is put into the tanning-drum, the temperature of the solution being 90° F. The skin is then placed in the drum, which is run steadily for 15 minutes and then stopped, the skin thrown back on the pins, the plug pulled out, and the salt solution drained off. The plug is then replaced and about ten pounds of common salt and eight gallons of water to 100 pounds of skins is put into the drum. The skin is milled in this solution for about five minutes, and then there is added to the salt water and skin one gallon of one-bath chrome liquor for 100 pounds of skins, in which the skin is milled for half an hour, when another gallon of the liquor is added and the skin milled again, this time for an hour, when a third gallon of the liquor is added, and the drum is run steadily for two hours for skins of average thickness, and three hours for heavy and thick skins. At the end of this time the skin should be well tanned, but in order to complete the process and have the skin thoroughly tanned, it is necessary to add one half-pound of bicarbonate of soda dissolved in two quarts of warm water, and to have the skin milled for about three quarters of an hour. The skin is next removed from the liquor, allowed to drain for 24 hours, and then washed. For washing tanned leather, two pounds of borax is used for 100 pounds of skins. The skin is now washed for a few minutes in clear water and either struck out or pressed and shaved, after which it is ready for the coloring, fat-liquoring, drying-out, and finishing.

The introduction of patent and enameled leathers marked a notable step in this industry. The composition made by Seth Boyden more than 50 years ago induced leather manufacturers to prepare a leather for its acceptance. The first leather made was in oak and hemlock bark liquors. At that time the only known means of splitting hides was by the Union splitting-machine, operated by hand. The hide was partially tanned and then split on this machine, dividing it into three parts—the slab or leveler, used for shoe purposes such as insole stock; the next, known as a dash-split; and the upper part, called the hide or grain. The hide and the dash-split were then returned to the liquors and thoroughly tanned, after which the hide was taken by the currier and buffed on a beam in a wet state, as it was found to be impracticable to japan with the Boyden compositions on the natural grain. After the hide was buffed and the grain divided, the hide and the dash-split were taken to the "japanery" and coated in the following manner: The first coat, called "sweet-meats" by the mechanics, was made of raw linseed oil, to which, after boiling for 24 hours in heats varying from 400 to 550 degrees, umber and lampblack were added. After boiling, the mixture was cut with turpentine, so that the

LEATHER

japanner could spread it on the surface of the hide with a steel slicker. When coated, the hide and split were placed in ovens operated with slides, and dried in heats running up to 160° F. After each coat was dried, the rough surface was ground off by using pumice-stone, and no less than two or three coats, according to the character of the leather, were applied. The leather was then in readiness for the finishing, or varnish coats. This varnish was made by boiling linseed oil in the same manner as the sweetmeats, and adding thereto Chinese blue-lumps, in a proportion of about four ounces to the gallon of oil. The varnish, like the sweetmeats, was reduced with turpentine, and from 1 to 11 coats given the leather, according to the face and finish desired. After this was done the leather was taken from the ovens and exposed to the sun-shine, which set the finish and the lustre. The leather was then taken off the frames, placed in a cooling-cellars, and left there from 24 to 48 hours, after which it was measured and ready for sale. In the manufacture of patent leather the use of turpentine for reducing compositions was not only dangerous, since combustion was probable, but also injurious, as it went to the brain of the operator, and often blood would run from the nose and ears as a result of congestion. A man japanning could not stand the fumes for over half an hour at a time. However, as time went on, turpentine was done away with and its place taken by naphtha, a product of petroleum, and to-day nine tenths of all shiny leathers are made with naphtha as a reducer of the compositions.

For years after the first patent leather was made, only what was known as hand-buffed could be produced, as the grain had to be cut off by the currier, on the beam, and the part taken off was useless. By this time, in the 70's, the Union machine had been improved to such an extent that the hide could be buffed on it, and instead of a part being thrown away, it was finished for pocketbook, bookbinding, and hat-sweat purposes, in all of which it took the place of roans and sheepskin skivers, and the hide from which it was taken was made into what was known as machine-buffed, patent, and enameled leather. Machine-buffed patent leather for carriage and other purposes has been sold for from eight to ten cents less per foot than the hand-buffed leather was and is now sold for. Later the manufacturers were enabled, with the advent of the endless-knife machine, to take off a lighter buffing than with the Union machine, and also to take off a heavier one if desired. This led to the use of the heavy buffing for shoe-tipping, and attracted the attention of the patent-leather men generally to the possibility of competing with France and Germany in the making of shiny leathers, not only for tipping, but for vamps as well. For many years this competition went on with indifferent success, until the chrome tannage was introduced, and the shoe-trade found that its application to all kinds of skins produced upper leather superior to the best bark and sumac tannage.

To the manufacturer of patent and enameled leather is largely due the cheap patent shoe-leathers that are in the market to-day, and which seem to have come to stay. Manufacturers experimented with the chrome process until they

were enabled to split cow, steer, and horse hides successfully out of the limes, and then tan the grain in one-bath or two-bath chrome liquors. After they had accomplished this, they found that in order to enable them to make up their chrome-tanned grain into shiny leather for vamp purposes, that would last without cracking or opening, they would have to change from the old compositions and invent such as would enable them to finish the hide in the grain without buffing and with one varnish or finish coat, instead of from three to seven as before. Their success is known to the trade, and it is now in order to note the difference between the old and the new compositions, that of Seth Boyden and that in present use. To-day the most successful manufacturers are making their compositions as follows: The under-coats are made of a solution, the component parts of which are guncotton, amyl acetate, linseed-oil, Prussian blue, nigrosine, and other mineral colors. By the old process it took from 24 to 48 hours to soak the hide, and from eight to ten days to unhair and bathe them. After that the hide was struck sufficiently through for sammying and splitting, which took 21 days. The splitting took in actual machine-work and preparation six days or so, and it required at least ten days more or retain the parts. The leather was then set out and dried on stretching-frames, after which it was softened, patched, and otherwise prepared for japanning, the whole of the latter process taking about ten days, according to the time it took to dry, which was never done by heat. In the japanning the hides were tacked on frames, and a day was allowed for each coat to dry, up to the time of the last varnish-coat, which was allowed a little more time. The sunning, stripping, and swelling ordinarily took about three days, making in all 72 days to finish hides into leather.

The manufacturing of leather by the chrome process, where manufacturers use the old method of unhauling and bathing, would need as much time as in the old process, but the most successful manufacturers consume time in the production of their leather as here stated: Soaking and hairing require three days; killing the acid in this process, three days; all the fleshing and other beam-house work, done in the old process by hand, they now do by machinery; two days are allowed for preparing and splitting, and five days for tanning, coloring, fat-liquoring, and dripping; one day is then allowed for table-work, and four days for sammying, staking, and drying, after which the hide is put into sawdust for two days to moisten, then stretched and drystaked, for which two days are allowed; four days are given for japanning, after which the hide is put in the sun for part of one day, two days being allowed after this process for swelling; making in all 27 days—a saving of almost two thirds in time. Except the japanning, which is still done by hand, nearly all the work done under the old process by skilled labor is done under the new chrome tannage by machinery. It must be remembered, however, that when the manufacturer of the chrome upper-leather splits the hide, the split and slab do not generally go back to chrome, except where the manufacturer is able to produce from a chrome-tanned split an article of commercial value. He puts his split

LEATHER

through the old bark-tannage process, in order to find a market for it, as he did before. A comparison of these two processes, and the material used, will show that the present cost of tanning, up to the japannery, is less than one half the cost of the old bark-tannage; but in the japanning, including the compositions used on chrome leather, the new process is nearly twice as costly as the old. See also HIDES AND LEATHER; TANNING.

J. GODDARD BROWN,
New York Manager of 'Shoe and Leather Reporter.'

Leather, Artificial. Owing to the demand for leather being in excess of the supply, many fabrics have been introduced with the intention, more or less successful, of supplying its place. An article of this sort known under the name of leather cloth, was first produced in America about 1849, and was brought well under the notice of the British public at the Exhibition of 1851. A textile fabric (generally unbleached cotton, calendered to make it smooth) is coated with linseed-oil, turpentine, lampblack, and other ingredients. It is then scraped with a knife to produce a uniform surface. It is afterward dried in a heated oven, and is passed between rollers covered with pumice dust to rub the composition smooth. These processes are repeated several times. Three or four coats of a sort of enamel paint are then applied. The grain of morocco leather is imitated by passing the cloth between grooved rollers; or patterns in relief may be obtained by passing it between embossing rollers. Another kind of artificial leather is made of leather parings and shavings reduced to a pulp, and then molded into buckets, machinery bands, picture-frames, and other useful and ornamental objects. Vegetable leather consists of caoutchouc dissolved in naphtha, spread upon a backing of linen. All odor of the naphtha is removed by a chemical process, and the fabric may be made of any thickness by additional backings of linen cemented with the caoutchouc. Its strength is almost marvelous, and it can be produced at about a third of the price of leather. It may be used for table-covers, carriage-aprons, soldiers' belts, harness, bookbinding, etc. It has several advantages over leather proper, among which we may mention, that however thin the imitation is, it requires considerable force to tear it; it is impervious to damp; moisture may remain long upon it without injuring it, and its polish is increased rather than decreased by friction. Various other substitutes of leather have been recently introduced, consisting of the application of oily pigments to cloth, or thin layers of leather attached to cloth, felt, or other backing by caoutchouc cement.

Leather, Chamois. What is known in the market as chamois skin is really an oil-tanned sheep or lamb skin lining. The supply of skins from the chamois animal is very limited; enough could not be obtained in a year to supply the United States for more than a single day. In Switzerland about five thousand to six thousand skins would be a fair average yearly crop. This skin is heavier than the skin of the sheep or lamb, also much coarser. For strength and durability this skin is preferable, but for ordinary use and appearance the oil-tanned sheep

skin lining would, in most instances, be preferred.

To manufacture sheep or lamb skins into chamois leather the first step necessary is to remove the wool, which is accomplished either by painting the skin on the inside with a solution of sodium sulphide or by immersion in milk of lime. By the former method the wool is loosened in a few hours; by the latter method it will require several days. When the wool is loose, it is pulled off either by hand or scraped off with a dull instrument. The skin is now again immersed in milk of lime, to swell it. It is then cleaned (beamed, as the trade calls it), to remove all fleshy particles that may adhere to it. It is now ready for splitting. The chamois skin is really only the half of a skin. The outside, that is, that part of the skin next to the wool, known as the grain side, is not suitable for chamois leather, and is used for other purposes, mostly for hat linings, book covers, etc. In former times, when skins were prepared for oil tannage, this part of the skin was cut away with a suitable knife and thus lost. In our days the skin is cut through the centre (split), thus producing two skins from one—the outside, called grain or skiver, and the inside, called lining or flesher. The splitting is accomplished on machines specially constructed for this purpose. It consists of an endless knife, the edge of which is constantly grinding to keep it sharp, the skin being passed through rollers against the sharp edge of the knife. These machines require very delicate adjustment to produce good results.

The lining or flesher is now ready for tanning. This is accomplished by sprinkling it with oil, codfish oil of good quality. It is important that this oil should be thoroughly incorporated into the skin. For this purpose a quantity of the skins are placed into what are known as fulling stocks, which twist and turn the skins in every direction, and distribute the oil evenly. After sufficient milling the skins are partly dried and the process of sprinkling and drying is repeated again and again until they are full of oil, and all the moisture is dried out. They are now allowed to hang sufficiently long to thoroughly tan them at a temperature of about 100 degrees. The process after this is very simple. The oil is removed by pressure, and the balance washed out by saponification; after this they are dried and they are then ready for finishing. The oil, by the way, is recovered, by decomposing the soap solution with an acid and separating. It is sold to manufacturers of other leathers, it being useful to make them pliable, etc. The finishing is done mostly by pressing the skin against revolving wheels, covered with emery or flint to remove all adhering substances and to present a finished surface. We now have the finished chamois leather ready for the trimming and sorting room, where it is cut into suitable sizes and packed for the market. Of late years, a trimmed skin, that is, skins of even sizes, are preferred by the trade. For this reason most manufacturers, at least most American manufacturers, cut their skins over patterns so as to produce uniform sizes. In former years, when England and France supplied the United States market, the skins in the same package would vary in size and shape, thus lacking uniformity. See also HIDES AND LEATHER.

LEATHER-BACK — LEAVES

Leather-back, or Leather-jacket. See LEATHER-TURTLE.

Leather-beetle, one of the dermestid beetles (see DERMESTES), which in the grub state damages leather in storehouses and after it is made up into articles, such as shoes, harness, etc. The species is *Dermestes vulpinus*; and it is also a pest in silk manufacture, eating the cocoons. Infested places should be thoroughly fumigated with bisulphid of carbon, or some other powerful gas.

Leather-fish. See FILE-FISHES.

Leather-head, an Australian bird, the friar-bird (q.v.).

Leather Turtle, or Trunkback, a rare marine turtle of the tropical seas (*Sphargis coriacea*), which has a leathery case instead of a shell. It is the largest of existing *Chelonia*, known specimens having a case four feet in length, and a live-weight of not less than 1,000 pounds. When young its case is thin, soft and flexible, but as age advances the jacket becomes stiffened by the formation within it of great numbers of little adjoining bony plates; and the exterior shows strong longitudinal ridges. These turtles are powerful swimmers and wander throughout the oceans, feeding upon jellyfishes, crustaceans, cuttlefishes and other animal food. Late in the summer it seeks some sandy shore or islet, where the female buries her eggs after the manner of other sea-turtles. These eggs are good to eat, but the flesh of the animal is not of good taste, and is said to be unwholesome. Much interesting discourse upon the curious structure, relationships and ancestry of this declining race may be found in Gadow's 'Amphibia and Reptiles' (London 1901).

Leatherstocking Tales, a name given a series of Indian and pioneer romances by James Fenimore Cooper (q.v.). The name Leatherstocking was given to Natty Bumppo, one of Cooper's heroes.

Leatherwood. See CYRILLA.

Leavenworth, lēv'ēn-wért̥, Elias Warner, American lawyer: b. Canaan, N. Y., 1803; d. Syracuse, N. Y., 1887. He graduated at Yale College in 1824; studied law with William Cullen Bryant at Great Barrington, Conn., admitted to the bar in 1827, and began practice the same year at Syracuse, N. Y. He was secretary of state of New York, 1854-5; president Board of Quarantine Commissioners, 1860; 1875 to 1877 he was a member of Congress. He published 'Genealogy of Leavenworth Family' (1873).

Leavenworth, Kan. the county-seat of Leavenworth County and one of the most important cities in the State, 26 miles northwest of Kansas City, on the west bank of the Missouri River, here spanned by two fine iron bridges, accommodating railway and ordinary traffic. The Missouri P., Union P., Atchison, T. & S. Fe, Kansas City N. W. and C. G. W. R.R.'s enter the city, which also is the eastern terminus of the Kansas Central Railway, and the Rock Island and Burlington systems. Leavenworth was founded by the "Sons of the South" in 1854, and the following year received a city charter. During the negro-emancipation agitation it was a strong pro-slavery centre. It derives its name from Fort Leavenworth north

of the city, the oldest and most important military depot on the Missouri River, built in 1827. Leavenworth is the trade centre for a farming and coal-mining region, an inexhaustible coal deposit underlying the city at a depth of 700 feet, giving employment to over 1,000 miners, and yielding 60,000 bushels of coal daily. Besides its coal mines, the manufacturing industries are correspondingly extensive and include flour-mills, woolen-mills, iron foundries, manufactures of mill machinery, mine machinery, steam-engines, lumber, furniture, saddlery, brooms, baskets, buggies, wagons, shoes, patent medicines, bags, ice, crackers, candy, cycles, and dye-works.

The city, which is protected from inundation by a limestone stratum, is well laid out, electrically lighted, has an excellent water supply, and a complete system of electric street railroads, connecting with Fort Leavenworth on the north, and the National Soldiers' Home on the south. The principal buildings are the Catholic pro-cathedral of the Immaculate Conception, over 25 churches of all denominations, the Kansas State Orphan Asylum and protective home, Cushing and St. John's hospitals, two theatres, three national banks, two savings banks, etc. The educational institutions include Mount St. Mary's Academy, a high school, State normal school, and the Whittier library. The suburban Soldiers' Home accommodates 3,000 veterans of the Civil War, and is situated amid attractive grounds. A garrison of 12 companies of United States infantry and four troops of cavalry occupy Fort Leavenworth; the United States Infantry and Cavalry School for the instruction of army officers, and the United States military prison holding 800 prisoners are also situated here, and a mammoth bronze statue of Gen. U. S. Grant. The city is administered by a mayor and council elected biennially. Pop. (1890) 19,768; (1900) 20,735.

Leaves, in the ordinary sense of the word, are the structures on which devolves the duty of nourishing the plant. They invariably arise as lateral protuberances from the growing-points or terminal vegetative cones of the shoots, that is, from a part of the plant which is still in an embryonic condition. In cases where a leaf seems to arise from an older part of a plant, as from the trunk of a tree, close inspection shows that it is really developed from a shoot perhaps not readily visible. Its growth is first at the apex, but this soon ceases, and is followed by continuous enlargement throughout the tissues, by which the upper part or blade of the leaf is soon distinguished from the basal part, and the stalk or petiole (where present) is subsequently formed between them. The development may result in a variety of structures, some of which are far different from typical foliage-leaves, yet are strictly homologous; such are scale-leaves, bracts, and the parts of a blossom (floral leaves). The higher the rank of the plant in the scale of development the more these diversities are manifested; and the observations here to be made apply mainly to the phanerogams from the ferns (q.v.) upward.

Leaves collect from the atmosphere the great essential of plant-food, carbon, and conduct the processes of its assimilation, or, in other words, apply it by chemical conversion to the vitality and growth of the plant. In order to under-

LEAVES

stand how they perform this function it will be necessary to investigate their structure and properties. Each leaf is composed of three parts, an outside layer on each surface of compact, flattened, and usually colorless cells, forming a skin or epidermis; an inner part (mesophyll) consisting of irregular cellular tissue and inter-cellular spaces. These cells of the mesophyll contain minute bodies (chloroplasts) of green coloring matter called chlorophyll, which also abounds in the bark of the stems of herbs and all other green parts of plants, and is the working element in their composition. Through the spongy mesophyll extends the network of veins which form the skeleton of the leaf, and are at once its support and its channels of communication with the other parts of the plant; these form the third part of the leaf. One other important feature must be mentioned—the breathing-pores, or stomata. These are excessively minute openings in the epidermis, which occur wherever chlorophyll lies underneath, but are most numerous on the under or earthward side of the leaves, where, on the average, about 60,000 may be counted per square inch of surface, although in some leaves they are six or eight times as numerous. Each of these pores lies between the "guard-cells" which form an automatic valve, opening or closing the pore, by their swelling or shrinking, according to varying conditions and the requirements of plant-health, especially in respect to evaporation. The chlorophyll grains (chloroplasts) also change their positions in the cells so as to take all possible advantages of a weak illumination, or to guard against a bad effect from excessive light.

Of the ten essential elements of plant-food nine are drawn from the soil by means of the roots, but the tenth, which is the most important and the largest in amount of all, is obtained by all green plants solely from the carbonic acid of the atmosphere, and is taken up by the green leaves alone; also a little of the oxygen required. The air enters the stomata, is seized, as it were, by the chlorophyll, and within it is so decomposed (in a manner not yet explained) that the carbon is chemically extracted and is transformed into plant-food and plant-substance, that is, is assimilated; and botanists restrict their use of the term "assimilation" to this physiological absorption of carbon alone. In order to be able to do this work, however, the leaves require the aid of sunlight, without which the chlorophyll becomes inactive, and in total darkness a green plant will speedily die of starvation, however rich may be the soil in which it is rooted. The "rest" of plants at night is thus accounted for; and also the greater rapidity of growth in northern plants where in summer they enjoy more hours of sunlight each day than southern plants get.

But the service of leaves in the nutrition of the plant does not cease here. They perform a most important function in the transpiration of water. Plants must always draw from the soil a quantity of water far in excess of their needs, or of their capacity to hold, in order to get a sufficient supply of the mineral food dissolved in it, but in exceedingly small quantities; and after that sustenance has been extracted the extra useless surplus of water must be got rid of. This is accomplished through the

stomata of the leaves, out of which water is always passing in gaseous evaporation, or sometimes even in globules. A secondary, but most important accompaniment of this is the suction thus formed, by which the constant up-flow from the root-ends is maintained.

A third essential office of leaves is as the lungs of the plant, which must breathe in essentially the same manner and for the same purposes as does an animal; that is, they must take up oxygen and give off carbonic acid. This independent process (the converse of the simultaneous assimilation) is carried on steadily by all plants, night and day; but in those having leaves it is mainly performed by these organs, because they spread the greatest surface.

In addition to these foremost and general services, leaves are adapted in particular cases, almost as numerous as the plant species, to such special purposes as a depository of food for the young plant in the cotyledons or seed-leaves; as bulb-scales in plants like the hyacinth and lily, where part of the nourishment in the foliage of one year is stored up in the scales or subterranean thickened leaves, for the early growth and flowering of the next year; as bud-scales, forming the protective coverings of buds, as tendrils, pitchers, fly-traps, etc.

These complicated requirements and duties, under varied conditions and circumstances, have produced the extraordinary modifications of form and texture which leaves present, and which must now be briefly considered.

Forms and Arrangement of Leaves.—The typical and ordinary foliage leaf is a thin flat structure composed of stalk (petiole) and blade (lamina) of symmetrical form, and growing in the plane of the horizon, so that one side (the dorsal) is presented upward to the sky and sunshine, and the other (ventral) is downward and in shadow; and these sides usually present appropriate differences in texture, the upper surface being usually more smooth and compact than the lower. A great variety of textures, from smooth, polished or waxy, to rough, downy or spiny, are distinguished by botanists, and used in the description of plants; these variations of surface are largely defensive in their character. Some leaves have no stalk, and are said to be sessile, in which case the base of the leaf may partly clasp, or completely surround the stem, or be otherwise modified; similarly the stalk takes many forms, sometimes with two lesser subsidiary leaves (stipules) at the base. The rigid woody centre of the stalk may continue straight on through the middle of the leaf to its apex, forming a midrib which throws out branches alternately on each side toward the margin of the blade, each again branching repeatedly and connecting with its neighbor, and so forming a network or skeleton of woody fibres which strengthen and support the leaf. These ribs are called veins or nerves, and the whole is the "venation" of the leaf. Such a simple leaf (for example of the beech) is called reticulate or net-veined. In a large class of cases, however, the branches of the midrib do not spring at approximately equal intervals along its length, but all diverge from a point near its base, making a palmately veined arrangement, as in the maple. This reticulate veining is characteristic of dicotyledons. In another very distinct type of venation, character-

LEAVES OF GRASS—LEAVITT

istic of monocotyledons, there is no midrib, but the stalk divides at the base of the blade into many equal veins which extend in a more or less curving line through the length of the leaf, converging at the apex; such a leaf is said to be parallel-veined, as in grasses. Upon the plan of the skeleton depends mainly the form of the leaf, of which a great number of variations are named in botanical manuals and used in descriptions of species, depending mainly on the character and extent of the indentation or incisions.

The arrangement of leaves upon the plant is an important matter. That it follows certain regular plans is apparent in buds, which when cut across exhibit their young leaves packed together in one or another of certain definite ways; and their relative position on the stem of an herb or the twig of a tree follows as a result of the law of growth in that group. The theoretical perfection of arrangement, however, is often greatly disturbed by the interference of older leaves with the development of the younger, and by other causes affecting the unsymmetrical growth of the whole plant. The arrangement of leaves upon the stem, called *phyllotaxis*, is in most cases one of alternation, thus securing the uninterrupted exposure of the upper surface of the leaf to the sun. It is to obtain this exposure that plants struggle to become tall, and bear their leaves most profusely at the summit; and that the branches of trees reach outward as far as possible; and the lower early leaves of many soon die off because shaded by the later, higher growth. The arrangement is carried out in two principal ways: the leaves are either alternate, one after another, only a single leaf arising from each node or joint of the stem; or opposite, when there is a pair of leaves on each joint of the stem; but sometimes the leaves are whorled or verticillate, there being three or more in a circle on one joint of the stem. The result of this arrangement in an alternate-leaved stem is to cause the leaves to follow one another up the stem in a spiral manner; while any two successive leaves on the same species will also be separated from each other by just an equal portion of the circumference of the stem. The same principle governs the parts of the flower (q.v.) in which the sepals of the calyx typically alternate with the petals of the corolla, the petals with the stamens, and the stamens with the pistils, but it is often disguised in a very puzzling way, especially by the absence of one or more series of organs. See FLOWER.

Modifications of Leaves.—Leaves exist in other forms than the typical ones of foliage. Scales, such as those which envelop and protect buds in winter, and the seeds in cones, are leaves of simple structure which have no assimilative powers or functions; they most frequently originate from an enlarged leaf-base upon which a proper leaf never develops. Bracteal leaves, or bracts, are of similar character, and grow beneath and about the flowers, of which, when they are colored, they often form the most conspicuous part; but frequently they are green and are connected with true leaves by intermediate forms. Both scales and bracts have been forced, under experimental conditions, to develop into true leaves.

The modified leaves which form the flowers of phanerogams are termed "floral leaves," and,

as has been said, typically succeed one another in whorls from below upward, as sepals, petals, stamens and carpels. The sepals are usually green and much like foliage-leaves; the sepals often retain a likeness, but the interior whorls usually bear no resemblance to leaves, yet occasionally, in ill-health, revert to a shape which betrays their origin and genetic history.

Periodicity of Leaf Growth.—Leaves are a temporary part of the plant, arising and disappearing at more or less regular intervals, usually once a year. This is especially noticeable in the higher plants, some of which (annuals) die in autumn completely, surviving as species only in their seeds; others die down to the roots in the fall and put forth entirely new stems as well as leaves the following spring; while others, as shrubs and tree, die only so far as their leaves are concerned, putting forth new foliage after the stated period of rest. This period is due to the arrival of annually recurring unfavorable conditions of temperature or moisture or both, when the activity of life in the plant is suspended and it ceases to feed or grow. In such a state leaves having no function are needless—in fact often harmful—and in many cases die and fall off in so sudden and conspicuous a manner that we say such trees are deciduous; while others, which we call evergreen, retain most of their leaves in a green condition until gradually replaced by new ones, so that the foliage seems to be perpetual. The brilliant colors of the dying leaves of many trees and herbs in autumn are due partly to chemical changes in the decaying chlorophyll, and partly to the exposure of pigment cells previously concealed by the abundance of chlorophyll and other features of vital activity. The leaf drops because it no longer receives nourishment from the stem or twig. The cells at its base close up, transmitting no more sap, and in so doing separate from those in the base of the leaf, which is thus cut off and thrown away.

Bibliography.—The morphology, genesis, and functions of leaves have been studied most deeply by German students, as Haeckel, Fritz Müller, Göbel, Schwender, Marchlewski, Fisher, and others. These and other authorities have been well summarized in the English translation by Porter of Strasburger's "Text-book of Botany" (1903). For the forms and nomenclature of leaves, see the botanical manuals and text-books of Gray, Wood, and other American authors.

ERNEST INGERSOLL.

Leaves of Grass, a collection of fleshy poems by Walt Whitman (q.v.) published in 1855.

Leavitt, lē'vít, Joshua, American editor: b. Heath, Mass., 8 Sept. 1794; d. Brooklyn, N. Y., 16 Jan. 1873. He was graduated at Yale College in 1814 and was admitted to the bar in 1819. In 1825 he graduated at Yale Divinity School and in 1831 became editor of the New York "Evangelist." He was an active member of American Anti-Slavery Society in 1833, and from 1837 to 1840 was editor of the society's journal, "The Emancipator." He was an active promoter of the "Liberty" and "Free Soil" parties. In 1848 he became one of the editors of the "Independent," retaining a position here until his death. He compiled "The Christian Lyre" (1834).

LEBANON

Lebanon, lēb'a-nón, Ind., city, county-seat of Boone County; on the Chicago & S. and the Cleveland, C., C. & St. L. R.R.'s; about 30 miles northwest of Indianapolis. The first permanent settlement was made in 1824, and the city was chartered in 1875. Its chief industrial establishments are flour and lumber mills, grain elevators, novelty works, and a natural-gas plant. The government is vested in a mayor, whose term of office is four years, and a council. The waterworks are owned and operated by the city. Pop. (1900) 4,465.

Lebanon, Ky., city, county-seat of Marion County; on the Louisville & N. railroad; about 52 miles southwest of Lexington, the capital of the State, and 70 miles south of Louisville. It is situated in an agricultural region, and is the trade centre for an extensive section. The chief manufactures are flour, meal, whiskey, furniture, wagons and carriages. A large amount of live-stock is shipped from Lebanon. It is the seat of Saint Augustine's Academy, under the auspices of the Roman Catholic Church, and of a public and parish high school and good graded schools. Several churches, and the city and county buildings are among the prominent buildings. The city owns and operates the waterworks. Pop. (1900) 3,043.

Lebanon, Mo., city, county-seat of Laclede County; on the Saint Louis & S. F. railroad; about 55 miles northeast of Springfield, the capital of the State. It is situated in an agricultural region and is the trade centre for a large extent of country. Its chief manufactures are flour, machine-shop products, lumber, bricks, and dairy products. Its trade is principally in the manufactured products, live-stock, fruit, hay, and vegetables. The city is a well known health resort because of its mineral springs. Pop. (1900) 2,125.

Lebanon, N. H., town, one of the county-seats of Grafton County; on the Mascoma River, a few miles from its junction with the Connecticut River; and on the Boston & M. railroad. It is about 68 miles northwest of Concord, the capital of the State. It was settled about 1762, by people from the vicinity of Lebanon, Conn., who named their new home after the Connecticut town. It is situated in an agricultural region, but the extensive water-power supplied by the Mascoma River has made it an important manufacturing town. The chief manufactures are woolen goods, machinery, agricultural implements, wooden ware, men's clothing, sash, doors, and blinds, snow-shovels, flour, dairy products, and lumber. It has large brick-yards and granite-works. Over 1,000 persons are employed in the manufactories. The annual town-meeting is still the governing power. Pop. (1900) 4,965.

Lebanon, Ohio, village, county-seat of Warren County; on the Dayton, L. & C. and the Cincinnati, L. & N. R.R.'s; about 73 miles southwest of Columbus and 25 miles northeast of Cincinnati. It was laid out as a village in 1802. It is situated in an agricultural region and its industries are connected with farm products. It is the seat of the National Normal University, a private institution, which in 1903 had in attendance nearly 3,000 pupils. The Mechanics' Institute Library has about 5,000 volumes. There is one

orphan asylum. The city owns and operates the electric-light plant and the waterworks. Pop. (1900) 2,867.

Lebanon, Pa., city, county-seat of Lebanon County; on the Cornwall & L. and the Philadelphia & R. R.R.'s; about 66 miles northwest of Philadelphia and 23 miles northeast of Harrisburg. Lebanon was settled as early as 1700 by German emigrants. The borough of Lebanon was laid out by George Steitz, in 1750, and was first called Steitztown. It was incorporated in 1820 and chartered as a city in 1885. It is situated in the Lebanon Valley, noted for the fertility of its soil; but the largest part of the wealth of the city comes from the quarries and mines of the vicinity. The Cornwall iron mines, about five miles distant from the city, the limestone and brownstone at the base of the mountains, the brick-clay, the iron ore, all contribute to the industrial wealth of Lebanon. Its chief industrial establishments are furnaces and foundries, rolling-mills, steel-plants, machine-shops, a very large nut and bolt works, chain-works, a creamery, employing a total of about 10,000 persons.

The educational institutions are the public and parish schools, the Lebanon Business College, the School of Telegraphy, and four libraries. It has a large number of churches. Some of the prominent public buildings are the courthouse, county-house, and post-office. There are six banks with a combined capital of \$700,000. The annual business amounts to over \$10,000,000. The predominating nationalities are, in order of numbers: American (a large majority), Irish, Germans, Hungarians, Italians, and a few Chinese. Pop. (1890) 14,664; (1900) 17,628.

JOHN W. HARESON,
Ex-Mayor.

Lebanon, Tenn., town, county-seat of Wilson County; on the Nashville, C. & St. L. railroad; about 35 miles east of Nashville. It is situated in an agricultural region, and its trade and industries are connected with farming products. It ships large quantities of hay, butter, and poultry. It is the seat of Lebanon College for Young Women, and of Cumberland University, founded in 1842 by the Cumberland Presbyterians. Pop. (1900) 1,956.

Lebanon, Cedars of. See CEDAR.

Lebanon, Mountains of, Syria, two nearly parallel mountain ranges which, commencing at about lat. $34^{\circ} 25'$ N., stretch south-southwest toward Palestine, enclosing between them a valley about 70 miles long by 15 miles wide, now simply distinguished by the name of El-Bukaa, "the valley," but known anciently by the name of Coel-Syria. To distinguish the two ranges that on the west is called Lebanon, and that on the east Anti-Lebanon; the Arabs, call the former Jebel-Libnan, and the latter Jebel-esh-Shurky. Lebanon, which runs almost parallel to the Mediterranean coast, and at no great distance from it, may be considered as terminating near the coast, a little north of the mouth of the Litani, between Tyre and Sidon. It is the loftier range of the two, and presents almost a continuous ridge without any marked break. Its loftiest summit—Dhor-el-Khodih, in the north, has a height as given by barometer of 10,060 feet. Anti-Lebanon has a much lower average height, and the culminating point of this

LEBANON SPRINGS — LEBEL

chain Jebel-esh-Sheikh, situated west-southwest from Damascus, has a height stated to be about 9,000 feet. The prevailing rock of Lebanon is limestone, of a whitish color; and from this its name, which means "white," is supposed to be derived, though others ascribe it to the snows which cover it. The loftiest summits of Lebanon, presenting lofty precipices and wild narrow gorges, are almost absolutely barren; but at some distance below, vegetation makes its appearance, the pastures become verdant, and, by means of artificial terraces, cultivation is successfully carried on upon rugged slopes where it would otherwise be impossible. The habitable districts are occupied toward the north by the Maronite Christians, a hardy and industrious race, and toward the south by the warlike Druses. Numerous villages and convents are to be seen on the sides and summits of the cliffs. The forests of cedar for which Lebanon was anciently celebrated are represented by a few groves on Lebanon, there being none now on Anti-Lebanon. (See CEDAR.) The other prevailing forest trees are firs and oaks. The vine is largely cultivated, and olive, fig, and mulberry trees abound. Considerable numbers of wild beasts, as the jackal, hyena, wolf, bear, and panther, inhabit the glens and higher peaks.

Lebanon Springs, N. Y., village, in the northeastern part of Columbia County; on the Lebanon Springs railroad; about 25 miles southeast of Albany. It is in a fertile agricultural region, and is a favorite health resort because of its mineral springs. A community of Shakers (q.v.) who live in the village and vicinity make brooms and baskets, and cultivate extensive gardens. They sell considerable garden seed. Pop. of the town 3,000; of the village 700.

Lebanon Valley College, a coeducational institution, founded, in 1867, at Annville, Pa. It is under the auspices of the United Brethren. The college has five courses which lead to the degree of Bachelor of Arts; and normal, art, music, and preparatory departments. It has 15 scholarships, and the productive fund, in 1903, was about \$162,000; the income from the productive fund and the tuitions was in 1902, \$15,442. In 1903 there were connected with the school 29 professors and instructors, and 460 students.

Le Bas, Philippe, fé-lép lē-bā, French historian and archæologist: b. Paris 17 June 1794; d. there 1861. At 16 he entered the navy, which he left three years later for the army and he shared in the campaigns of 1813-14. In 1820 he was chosen by Queen Hortense to act as tutor to Prince Louis Napoleon, now Napoleon III., with whom he remained until October 1827. After holding professorships at Paris successively of history and of the Greek language and literature, he was commissioned in 1842 by the French government to undertake a tour of archæological investigation in Greece and Asia Minor, during which he made many valuable discoveries. He published books on very varied subjects, embracing essays on classical inscriptions, editions of ancient authors, travels, ancient and mediæval history, politics, instruction in German, and translations from German and English. His best known works are his 'Explication des Inscriptions Grecques et Latines recueillées en Grèce' (1835-7), and 'Voyage

archéologique en Grèce et en Asie Mineure' (1847 et seq.).

Lebaudy Airship, The, a remarkable invention of M. Lebaudy, of Paris, France; an airship of the balloon type which is asymmetrical in form, its midship frame being situated slightly toward the front. The total length is 190.24 feet. The midship frame is situated at 81.67 feet from the prow and 108.57 from the stern. The extreme diameter of the balloon is 32.14 feet. With respect to the length of 190.24 feet we have thus an elongation of 5.6 diameters. In the entire median part of the section of the fusiform bag is not a complete circle, but a segment limited by a chord at its lower part. This means that the balloon presents a flat portion fixed to a linen-covered plane and held by a rigid frame which is attached to the side of the bag and, on the other hand, supports the suspension. The surface of the bag is about 13,000 square feet. Its weight, stitching included, is about 880 pounds. The car has the form of a flat-bottomed pontoon with pointed extremities. It is 15.75 feet in length, 5.25 in width, and 3.28 in depth. It is formed of a metallic frame. The motive power is furnished by a 40-horse-power motor cooled by a circulation of water and a radiator. The gasoline tank is placed beneath the car and the motor, as a measure of precaution against fire. A little compressed air is sent to it by means of a bicycle pump for feeding during the setting in operation. The exhaust pressure afterward suffices. The motor uses 30.8 pounds of gasoline per hour, say about 6 fluid ounces per horse-power. The motor actuates two double-bladed propellers arranged on each side of the car at the extremities of a hollow horizontal journal, in the interior of which revolves the driving shaft. The transmission to the propellers is effected through the intermediate of bevel wheels protected by casings. The most remarkable flight of the Lebaudy airship was made 12 Nov. 1903, and will no doubt mark a date in the annals of aerial navigation. The airship covered about 38 miles in 1 hour 41 minutes, and came back to the starting point. After passing over the Seine region to the west of Paris it crossed the Forest of Saint Germain, then entered the city by way of the Bois de Boulogne. The airship was then headed direct for the Eiffel Tower, which it reached, and landed just behind it, carrying out the original intention. At the start the operator had 640 pounds of ballast, and threw out 286 during the trip. The maximum altitude reached was 1,000 feet, and the mean 330 feet. As to the speed the airship made on this trip, it was reckoned at 22.4 miles an hour. See also BALLOON; FLYING MACHINE.

Lebel, Nicolas, French soldier and inventor: b. Angers 18 Aug. 1835; d. Vitre, Ille-et-Vilaine, 6 June 1891. He entered the Military School of Saint Cyr in 1855, served as captain in the Northern Army during the campaign of 1870, and became director of the Musketry School at Tours, and in 1883 at Chalons. The same year he was appointed member of the commission on securing an improved rifle for the infantry. The commission decided in favor of the small-bore rifle offered by Lebel, and known as the "fusil Lebel," which was introduced into the French army in 1886. He was

LEBLANC—LEBRUN

present as colonel at the battle of Sedan, but sickness cut short his military career, and in 1800 he was placed on the retired list. He was subsequently put in charge of the Inland Revenue Department at Vitre.

Leblanc, Nicolas, French chemist: b. Issoudun, department of Indre, 1766; d. 16 Jan. 1806. He studied medicine, was appointed surgeon to the Duke of Orleans and, after the Revolution, administrator of the department of the Seine. His name is associated with the process of converting common salt into carbonate of soda, a matter to which he turned his attention in 1786, when the Academy offered a prize of 2,400 livres for the discovery. His first endeavors did not yield a decisive result, but led to an accidental discovery by Dizé, an assistant of Jean Darct (q.v.) at the College of France, through which success was attained. With the Duke of Orleans and another, Leblanc and Dizé formed a partnership and began to make soda. The Revolution wrecked their enterprise. Despite his patent, secured in 1791, Leblanc was compelled by the committee of public safety to disclose the secret of the process, and the manufacture became open to all. After years of poverty and fruitless efforts for redress, he committed suicide. The discovery of the essential features of the process was assigned to him in 1855 by a commission of the Academy, although the claim of Dizé was strongly advocated. As to the value of the process itself there is no doubt. It has made soda cheap, thereby facilitating the manufacture of soap, the cleansing and bleaching of cloth, etc.; has promoted the manufacture of sulphuric acid, and thereby the utilization of metallic sulphides; and has originated the manufacture of chlorine and of bleaching-powder. The Leblanc soda-process is still in extensive use, but is now dependent more on its by-products than on its output of soda. One half of the world's soda is now made by the ammonia-soda or Solvay process. See Soda.

Lebrun, Charles, French painter: b. Paris 24 Feb. 1619; d. there 12 Feb. 1690. He was the son of a sculptor, but early turned his attention to painting and became the pupil of P. Perrier and S. Vouet. He was especially attracted by the Italian masters, examples of which he copied in the gallery at Fontainebleau so that in his fifteenth year his works won the patronage of Cardinal Richelieu. Chancellor Seguier provided means for him to visit Rome and during his residence there (1642-6) he studied under Poussin, at the same time paying much attention to the antique, and the paintings of the early masters. In 1646 he returned to France, and assisted in founding the Royal Academy of Arts and Sciences, in which he became professor, chancellor, and in 1683 director. He was also director of the Gobelins tapestry manufactory. In 1662 Louis XIV. appointed him court painter, ennobled him and made him curator of his art collections. He was meanwhile engaged in decorating the Apollo gallery in the Louvre. In 1668 the king appointed him superintendent of works in the building of Saint Germain. He also decorated with paintings the royal chateau at Sceaux, and designed the statues and fountains for the park, etc. In 1679 he undertook his greatest work, the interior

decoration of the palace at Versailles, and in the Great Gallery portrayed the achievements of Louis XIV. Very many paintings of his are still to be seen in the Louvre. His works are characterized by abundant invention and facility of execution; they reflect the spirit of the contemporary Italian school, but are marred by excessive straining after effect, flatness of design, and falsity of color-tone. His vast canvas, 'Portrait of the banker Jabech of Cologne and Family,' is in the Berlin Museum. He exercised a despotic influence over French art of his time. He wrote 'Traité sur la Physiognomie' and 'Méthode pour apprendre à dessiner les Passions.' Consult: Generay, 'Le Style Louis XIV.' (1885); and Jovin, 'Charles Lebrun, et les Arts sous Louis XIV.' (1890).

Lebrun, Charles François, shärl frän-swä lē-brü'ni, DUC DE PIACENZA, French administrator: b. St. Sauveur-Landelin 19 March 1739; d. near Dourdan 16 June 1824. He was appointed inspector of crown-lands, later entered the States-General and the Constituent Assembly, was appointed governor of Seine-et-Oise in 1791, sat in the council of Five Hundred, of which he was chosen president, and was made third consul by Bonaparte for services on the 18th Brumaire. In 1807 he reorganized the administration of the exchequer, and after a long retirement re-entered public life as governor of Holland in 1810. He translated the 'Iliad,' the 'Odyssey,' and the 'Jerusalem Delivered.' Consult his 'Memoirs' (1829).

Lebrun, Marie Louise Elisabeth, French painter: b. Paris 16 April 1755; d. there 30 March 1842. She was trained under Doyen, Joseph Vernet and Greutze and chose portrait painting as her specialty. She left a great number of portraits in oil and pastel. About 600 are identified as her works of which the most important are, her portrait of herself with her little daughter (in the Louvre); her portrait of herself in the Uffizi Gallery at Florence; Marie Antoinette with her three children (in the museum at Versailles). In 1783 she was elected a member of the Academy. During the French Revolution she took refuge in the various European capitals, where she painted portraits of the reigning princes, and members of their families; as well as of the most famous people of the time. Few works of hers are to be met with except in private collections. She published 'Souvenirs de ma Vie' (Paris 1837).

Le Brun, Napoleon Eugene Charles Henry, American architect: b. of French parents, Philadelphia 2 Jan. 1821; d. New York 9 July 1901. He was a pupil of Thomas U. Walter, the architect, and from 1842 to 1861 practised his profession in Philadelphia where his most notable work is the Roman Catholic cathedral in Logan Square. He removed to New York in 1861 and among structures there which were designed by him with his son, are the Foundling Asylum and the Metropolitan Life Insurance building in Madison Square.

Lebrun, Ponce Denis Ecouchard, pôns dĕ-nĕ à-koo-shär, called Lebrun-Pindare, French poet: b. Paris 11 Aug. 1729; d. there 2 Sept. 1807. His title 'Pindar' is due to the form and the mythological allusions of his odes, not to any large poetical merit, either in them or the lyrics; and as a satirist, he alternately groveled

LE CARON—LECKY

before and libeled the same men. His best odes are addressed to Buffon. He excelled in the composition of madrigals and epigrams; the latter relate for the most part to his quarrels with other authors.

Le Caron, Joseph, zhô-zéf lê kâ-rôñ, French missionary: d. 1632. He was a Franciscan, belonging to the congregation of Recolets. His work in Canada, which he reached in 1615, was chiefly among the Huron tribe, and he was the first European to explore the lake of that name. His indefatigable labors among the Indians met with scant success, though he left some valuable information concerning their language. After General Wolfe's capture of Quebec (1629) he was deported to England with others of the French population and never returned to the monastery which he had built in that city.

Lecce, ancient LYCIA, or LUPIA, southern Italy. The town is situated in the province of Lecce, on a plain between the Adriatic on the north, the Gulf of Taranto on the west, and the Ionian Sea on the south. It has many interesting edifices, especially churches and convents, some of which contain admirable works of art. At the gate of St. Biagio is a triumphal arch erected in commemoration of the entrance of Charles V. There is a public library and there are well-established day and evening schools and numerous charitable institutions. Lecce was very flourishing during the Roman period, escaped the barbarians, and in 1000 A.D. was governed by its own counts. Pop. 23,000.

Lecco, lëk'kô, Lake of (It. *Lago di Lecco*), the name given to the southeastern arm of Lake Como in Italy. Some of the large streams of the northern part of Italy flow into Lake Lecco. The town of Lecco and many pretty villages are on its shores.

Lech, lëch, a river which has its rise in the Alps, in Vorarlberg, in Switzerland, flows east and north until it enters Bavaria, after which its course is almost directly north to Donauwörth where it unites with the Danube. Its length is nearly 200 miles. It is not a navigable stream but it has extensive water-power. On this river, near Rain, about five miles below Donauwörth, Tilly was defeated and killed, 5 April 1632, by a Swedish force under Gustavus Adolphus.

Leche, lë-chë, in zoology, the *Onotragus leche*, from South Africa. It is a water antelope, frequenting damp, marshy places, and taking to impassable swamps. It goes in considerable herds, and may be known by the peculiar way in which it allows its horns to recline, almost touching the withers.

Lechford, Thomas, American colonial lawyer: d. about 1645. He came to the Massachusetts Bay Colony in 1638 and was the earliest lawyer in Boston. He was regarded with great suspicion by the colonial authorities on account of his profession, and the nature of his religious opinions, and he found extreme difficulty in making a living. He therefore, in 1641, returned to England, where his book, 'Plain Dealing, or News from New England,' was printed in 1642. It is a valuable source of information respecting details of early colonial existence, and in 1644 was reprinted with the new title, 'New England's Advice to Old England.' A modern edition, annotated by J. H. Trumbull (q.v.), appeared in 1867.

Lecidea, in botany, the typical genus of the *Lecidinae*. The apothecia have a border colored like the disk. It is very extensive, and is found in a great variety of situations, and at every season of the year. *Lecidea geographica* is sometimes sulphur-yellow and sometimes yellowish-green. If a yellow specimen be suspended over a solution of carbonate of ammonia, it becomes covered with carmine-red globules, gradually loses its usnic acid, and then becomes grayish-white.

Lecithin, lë-cï-thin, in chemistry, a name applied to several phosphoretted fatty bodies, of very similar chemical and physical properties, derived from brain substance, nerves, blood, gall, the yolk of eggs, etc., and also from some vegetable substances (maize, etc.), and which appear as constant constituents of the cell substance of organized bodies. It is a viscous body, insoluble in water, slightly soluble in cold alcohol, but very soluble in boiling alcohol and in ether. From its saturated solution in alcohol, it crystallizes in radially-grouped needles, which dry up *in vacuo* to a white powder. It may also be crystallized from glacial acetic acid. Every lecithin is a fat containing only two fatty acid radicals, the third hydroxyl group being replaced by ethylen-trimethyl ammonic hydrate (neurine) in combination with phosphoric acid.

Lecky, lëk'i, William Edward Hartpole, English historian: b. Newtown Park, near Dublin, 26 March 1838; d. London 23 Oct. 1903. He was educated at Cheltenham College, and at Trinity College, Dublin, whence he was graduated in 1859, and in 1861 published anonymously his first work, 'Leaders of Public Opinion in Ireland,' dealing with Swift, Flood, Grattan, and O'Connell, which appeared under his name in a new edition in 1871. An important 'History of the Rise and Influence of the Spirit of Rationalism in Europe' followed in 1861-5 and ensured him wide reputation as scholar and thinker. His 'History of European Morals from Augustus to Charlemagne' (1869) displayed a profound knowledge though its conclusions were not always sound. His most elaborate and valuable work is a 'History of England in the Eighteenth Century' (Vols. I.-II., 1878; III.-IV., 1882; V.-VI., 1887; VII.-VIII., 1890), in which he treats very fully of Irish affairs to the time of the Addington ministry. In a new edition of this history, published in 12 volumes in 1893, the chapters on Ireland were removed from their original context and arranged in a continuous narrative occupying the last five volumes. This work is in reality a history of civilization for the period covered; treating of the forces contributed to the making of 19th century England, whether of native or of foreign origin. Lecky's other works are: 'Poems' (1891); 'Democracy and Liberty' (1896), in which he arraigns modern British political life, and makes some comments upon Gladstone which once aroused considerable discussion; and 'The Map of Life: Conduct and Character' (1899). In 1895 he was elected to the House of Commons as member for the University of Dublin, and in 1897 was sworn of the Privy Council. In politics he was at first a Liberal and from 1886 a Liberal-Unionist with an undisguised aversion to democratic government. He became

LECLAIRE—LE CLERC

corresponding member of the Institute of France in 1894, and an honorary member of the Royal English Academy upon its organization.

Leclaire, Edmé-Jean, ēd-mā-zhō̄n lē-klär, French social scientist: b. Aisy-sur-Armancourt 14 May 1801; d. Herblay 10 Aug. 1872. At first a farm-worker, then apprentice to a mason, he afterward apprenticed himself to a house-painter in Paris, and in 1827 began the painting business on his own account. He proved remarkably successful, and soon took a leading position in his trade. In 1835 the principle of profit-sharing (q.v.) was proposed to him, and in 1842 he began to put it in practice in his own establishment, dividing the amount available in sums proportioned to yearly wages. A mutual-aid society which he formed in 1838 and reorganized in 1853 sustained itself from the latter year on the profits which were shared among the members. In 1864 the right to a division of the funds of the society was superseded by a system of retiring pensions. Leclaire was elected maire of Herblay in 1865. In the company which he founded his plan of distribution is still adhered to with continued success.

Leclaire, le-klär', Ill., village, in Madison County, adjoining Edwardsville, the county-seat and post-office; on the Toledo, St. L. & W., the Chicago, P. & St. L., and a spur of the Wabash R.R.'s; 18 miles northeast of St. Louis. It contains the factories of the Nelson Manufacturing Company, the residences of its officers, of a number of the employees, and of some others. The village was founded by the Nelson Manufacturing Company, which, in 1886, adopted what is known as the "profit-sharing plan,"—dividing the profits of the business with the employees. After testing this plan, it was decided that more and better service could be rendered to the employees by providing good homes and social and educational facilities, than by simply paying a contingent increase in wages. In 1890 the company acquired 125 acres of high, rich, gently undulating corn land, well adapted to growing everything from blue-grass to watermelons. The tract abuts on the railroads mentioned. Coal underlies the land and there are coal-fields nearby. About 10 acres are reserved for factory purposes, 10 for a campus and other public uses, and the remainder for homes and farming use. All of the improvements, industrial, educational, and the buildings for homes, were started simultaneously. The manufacturing establishments are (1903) five factory buildings, a power-house, a dry-house, and some miscellaneous buildings, all made of brick. There are about 250 employees, who are engaged in making plumbing goods of iron, brass, wood, and marble; all of which goods are made from the raw product up to the finished article. None of what is called "raw material" is manufactured here. Adjoining the factory acres are first the bowling alley and the billiard room, then the ball grounds, next the school-house, the lecture and dancing-hall, and a skating lake. There are winding roads made of cinders, kept smooth, sprinkled in summer, never dusty and never muddy. These roads are bordered by concrete and board sidewalks and trees. The houses built for the employees by the company may be purchased and, if desired, paid for in installments about equal to city rents. The houses are mostly three to six rooms, and are built on lots with from 50 to

100 feet frontage, by 140 to 180 feet depths. They have well-kept lawns, flower beds, shade trees, fruit trees, and gardens.

There is no political organization in Leclaire; all are subject only to the State laws. There are no rules, no "Don't" signs, no boss. No case of disorder has yet (1903) occurred. There are no saloons. The church needs are supplied by Edwardsville. There has always been a kindergarten, and an "Industrial School" has been founded, wherein the pupils work half the time at productive labor and study the other half. The pupils living at home are not obliged to work. Those from a distance get their tuition and living free; they learn how to work and acquire a trade at the same time that they learn from books and capable teachers. No examination is required for entrance. The school is prepared to teach all from the lowest to the highest grade, and the pupils are promoted as rapidly as the results of their work merit. The work in the school consists of house building, farming, and varied factory work. Whenever a pupil becomes sufficiently proficient to earn, at the regular value of his work, more than the cost of his schooling and living expenses, he is paid the excess in money. The intention is to civilize work, to take it out of the category of drudgery and put it in the list of arts and crafts, to make the pupils intelligent workmen and skilled craftsmen. In this school there is a weekly lecture on hygiene, given by an experienced, broad-minded physician. The village has a free library, and each winter a course of lectures is given, two each month, with occasional musicales. A singing school is held one night each week, and a bowling party for the school and the children also one night a week, and occasionally excursions to St. Louis. In the summer there are excursions from St. Louis to Leclaire, sometimes entire train-loads of children for a day's outing. Leclaire is founded and built on simple lines; the complex and strenuous are avoided, good-will, simplicity, and the domestic enjoyments are fostered.

N. O. NELSON,
Leclaire, Ill.

Le Clear, Thomas, American painter: b. Owego, N. Y., 1818; d. New York 1882. He painted portraits in London, Canada, before he had received any instruction in art, and left that place about 1832 for New York, where he made his principal residence. He was elected a national academician in 1863. Besides his portraits, which are clever in characterization and full of life and expression, he has painted many genres, such as 'Marble Players'; 'The Itinerant' (1862); and 'Young America.' Among his portraits are those of 'William Page' in the Corcoran Gallery at Washington; and 'George Bancroft' in the Century Club, New York.

Le Clerc, lē-klär, John, or Johannes Clericus, Swiss theologian: b. Geneva, Switzerland, 19 March 1657; d. Amsterdam, Netherlands, 8 Jan. 1736. He began to study theology and philosophy in his native town, and continued his studies at Grenoble, Saumur, Paris, and London. He gradually adopted the views of the Remonstrants, as the adherents of Arminius (q.v.) were then called. In 1684 he was appointed to the faculty of the Remonstrant College at Amsterdam; but in 1728 a stroke of

LE CLERC—LECOMTE DU NOUY

apoplexy deprived him of his power of speech, which he never recovered. His influence has been most widely felt through his writings, which are voluminous. He edited the 'Apostolic Fathers of Cotelarius' (1698), and the views he held about Mosaic authorship, inspiration and kindred topics seemed to anticipate some recent deductions from the Higher Criticism. Besides a Bible commentary he published: 'Bibliothèque universelle et historique' (25 vols. 1686-93); 'Bibliothèque choisie' (28 vols. 1703-13); and 'Bibliothèque ancienne et moderne' (29 vols. 1714-26).

Le Clerc, Sébastien. See CLERC, SÉBASTIEN LE.

Le Clerq, Chrétien, krā-tē-ōn lē klär, French missionary: b. Artois, France, about 1630; d. Lens, France, about 1695. He labored for six years on the Island of Gaspé as a Recollet missionary with others of his order (1651-61), and then built a house for the Recollets in Montreal with money collected in France. After resuming his unsuccessful missionary work at Gaspé he returned to France. His works are interesting as throwing a side light upon early Canadian history, but are tinged with ecclesiastical partiality for Frontenac, who favored the Recollets at the expense of the Jesuits. These works are: 'Nouvelle Relation de la Gaspésie' (1691); and 'Establishment of the Faith in New France' (English translation by John G. Shea 1881).

Lecocq, lē-kök, Alexander Charles, French composer: b. Paris 3 June 1832. He received his musical education in the Conservatory of the Capital, under Bazin and Halévy, and the earliest of his operas to appear was 'Le Docteur Miracle,' which had won the first Offenbach prize. His operetta 'Fleur de Thé' gained him the widest recognition. In this as in his later productions he followed the advice he had received from Offenbach, that the operetta should be elevated into a work of art. His principal operettas are: 'Les Jumeaux de Bergame' (1868); 'Gandolfo' (1869); 'Le beau Duncio' (1870); 'La Fille de Madame Angot' (1872); 'Girofle Girofia' (1874); 'La petite Mariée' (1875); 'Kosiki' (1876); 'Le Dompteur' (1877); 'Le petit Duc' (1878); 'La Rousette' (1881); 'Plutus' (1886); etc. They are 42 in number, and have attained the most remarkable popularity in France and elsewhere.

Lecompton, Kans., city, in Douglas County; on the Kansas River, and on the Atchison, T. & S. Fe railroad; about 15 miles east of Topeka. It was settled in 1854 by sympathizers with the slavery side of the question which was then before the people, in relation to the admission of new States. Lecompton was the headquarters of the pro-slavery men, and it was here that the Lecompton Constitution (q.v.) was framed, in the fall of 1857. The Lane University was founded here in 1865. The place was named in honor of Judge S. D. Lecomte, one of the early workers in Kansas. Pop. 500.

Lecompton Constitution, in Kansas history a form of territorial government, adopted by a convention held at Lecompton, Kan., in 1857, the legality of which in both form and action became a matter of dispute, and caused national discussion and congressional action. For several years prior to 1857 the slave question

had agitated the territory, and numerous bloody quarrels between the Free State settlers and the Missourians who came across the border into Kansas, added fuel to the strife. In June 1857 the territorial legislature, composed entirely of pro-slavery men, chosen at an election at which the free-state men had declined to participate on the ground of its illegality, met at Lecompton, and among other acts passed one providing for the election of a convention to frame a State constitution for Kansas. Meanwhile Congress had passed a bill declaring void all the enactments of the Kansas legislature on the ground that they were cruel and oppressive. The election for delegates to the constitutional convention was held 15 June, but the free-state men took no part in it. Only 2,000 votes were cast, while the legal voters in the territory numbered 10,000. The constitutional convention met at Lecompton in November and adopted a constitution, four sections of which related to slavery, declaring the rights of owners to their slaves to be inviolable, and prohibiting the legislature from passing acts of emancipation. This provision alone was to be submitted to the people at an election to be held 21 December. The ballots cast were to be endorsed: "Constitution with slavery," or "Constitution with no slavery," thus securing in any event the adoption of a constitution, several clauses of which, besides those submitted, were highly objectionable to a majority of the people. A provision was inserted preventing any amendment to the constitution previous to 1864. The promulgation of this constitution caused great excitement in Kansas.

At the election 21 December, the vote returned was 6,143, more than one half of which was from the counties along the Missouri border, whose total number of voters by the census did not exceed 1,000. Against the slavery clause there were but 569 votes, the free-state men generally abstaining from voting. The constitution being thus nominally adopted, an election for officers under it was to be held 4 January. At a special session the legislature passed an act submitting the Lecompton constitution to the direct vote of the people on the same day with the State election, and the result was 10,226 votes against it. Congress after a long discussion referred the matter to the people of Kansas at an election on 3 Aug. 1858, when the Lecompton constitution was again rejected by 10,000 majority. Meanwhile the territorial legislature had called another convention to meet in April to frame a new constitution, which was submitted to the people and ratified by a large majority, though by a small total vote. The territorial legislature met in January 1859 and passed an act submitting to the people the question of calling still another constitutional convention. Delegates were elected, and at a convention which met from 5 July to 27 July a constitution was finally adopted which prohibited slavery. This was ratified by a majority of 4,000 at the election 4 October, and the slavery question was at last settled and Kansas was admitted to the Union as a State 29 Jan. 1861. See also KANSAS; SLAVERY.

Lecomte Du Nouy, Jules Jean Antoine, zhü'l zhö'n äñ-twän lē kônt dü noo-ë, French artist: b. Paris 10 June 1842. A pupil of Gleyre, Gérôme, and Signol at the Ecole des Beaux Arts, he won there the second Prix de Rome in 1865,

LE CONTE — LECOUVREUR

and was afterward an annual exhibitor at the Salon. Among his canvases, somewhat dull in color but admirably correct in drawing and archaeological exactness, are: 'The Sorcerer'; 'Bearers of Evil News before Pharaoh'; 'Job and his Friends'; 'The Madness of Ajax'; and a portrait of Béranger.

Le Conte, lē kōnt, John, American physicist: b. Liberty County, Ga., 4 Dec. 1818; d. Berkeley, Cal., 29 April 1891. He was a son of Lewis Le Conte (q.v.). He was graduated from Franklin College in 1838, from the College of Physicians and Surgeons, New York, in 1841; in 1846-55 was professor of natural philosophy and chemistry in Franklin College; in 1856-69 was professor of natural and mechanical philosophy in South Carolina College; in 1869 became professor of physics and industrial mechanics in the University of California; was president of the university in 1876-81; and in 1881 again assumed his professional duties. Among his publications were: 'The Philosophy of Medicine' (1849); and 'The Study of the Physical Sciences' (1858).

Le Conte, John Eaton, American naturalist: b. near Shrewsbury, N. J., 22 Feb. 1784; d. Philadelphia 21 Nov. 1860. He was a brother of Lewis Le Conte (q.v.). In 1813 he entered the army as a topographical engineer, and in 1831 was retired with the grade of major. He published 'Monographs of North American Species of Utricularia, Gratiola, and Ruellia,' and other studies in natural history.

Le Conte, John Lawrence, American entomologist: b. New York 13 May 1825; d. Philadelphia 15 Nov. 1883. He was a nephew of Lewis Le Conte (q.v.). He was graduated from Mount St. Mary's College (Emmitsburg, Md.) in 1842, from the College of Physicians and Surgeons in 1846, became a surgeon of volunteers in the Federal army in 1862, and was later made medical inspector United States army, with rank of lieutenant-colonel. In 1873 he was chosen to the presidency of the American Association for the Advancement of Science. He was generally recognized as an important authority on entomology; and published on that subject: 'Classification of the Coleoptera of North America' (1862-73); 'List of the Coleoptera of North America' (1866); and 'New Species of North American Coleoptera' (1866-73).

Le Conte, Joseph, American geologist: b. Liberty County, Ga., 26 Feb. 1823; d. Yosemite Valley, Cal., 6 July 1901. He was a son of Lewis Le Conte (q.v.). He was graduated from Franklin College, Georgia, in 1841, from the College of Physicians and Surgeons, New York, in 1845; practised medicine at Macon, Ga.: in 1850 became a pupil of Louis Agassiz, whom he accompanied on an expedition to Florida; and later was professor of natural science in Oglethorpe University, Georgia, and of natural history in Franklin College. In 1856-69 he was professor of chemistry and geology in the University of South Carolina, and from 1869 until his death held the chair of geology in the University of California. During the Civil War he was chemist in the Confederate medicine laboratory and later in the nitre and mining bureau at Columbia, S. C. He was vice-president of the International Geological Congress in 1891, and president of the American Associa-

tion for the Advancement of Science in 1892. His contributions to geology include the determination of the character and age of the Cascade range; the description of the ancient glaciers of the Sierra Nevada; the development of what is called the "contractional theory" in mountain building; and researches in vein formation. He wrote also on optics, philosophy, biology, and other subjects. He was an editor of the 'Journal of Geology and of Science,' and published: 'Religion and Science' (1873), a collection of lectures; 'Elements of Geology' (1878), his best known book; a 'Compend of Geology' (1884); 'Evolution: Its Nature, its Evidences, and its Relation to Religious Thought' (1887); and other writings. Consult his 'Autobiography,' edited by W. D. Armes (1903).

Le Conte, Lewis, American naturalist: b. near Shrewsbury, N. J., 4 Aug. 1782; d. Liberty County, Ga., 9 Jan. 1838. He was graduated from Columbia in 1799, studied medicine, on his plantation of Woodmanston, Ga., established a botanical garden, particularly rich in bulbous plants of the Cape of Good Hope, and a chemical laboratory where he conducted numerous researches. He published nothing, but was of admitted aid to many botanists in their labors.

Leconte de Lisle, Charles Marie René, shär'l mä-rē re-nā lē kōnt dē lēl, French poet: b. Saint Paul, Ile de Bourbon (now Réunion), 23 Oct. 1818; d. Louveciennes 17 July 1894. When a young man he went to France, studied law at Rennes, and after a course of travel settled in Paris. His progress was slow, but gradually he gathered a group of young writers, and expanded his own work, whereby he won recognition as leader of the modern Parnassian school of poetry. It was some years before he found a publisher for 'Poèmes antiques' (1852), his first volume of real significance, but with 'Poèmes barbares' (1862) he gained an academic prize of 10,000 francs. In 1884 he published 'Poèmes tragiques,' and in 1885 appeared 'Derniers Poèmes,' a posthumous volume containing also critiques on his precursors in lyric poetry. His hand gave its impress to 'Le Parnasse contemporain,' a series of volumes published in 1866, 1869, and 1876, which is representative of his school, and in these some of his own most notable work was first seen. He also rendered valuable service to French literature by his superior translations of the 'Iliad' (1867), Hesiod (1869), the 'Orphic Hymns' (1869), the 'Odyssey' (1870), Horace (1873), Sophocles (1877), and Euripides (1885). In imitation of the Greek he wrote the dramas 'Les Erinnyses' (1872) and 'L'Apollonide,' based on the 'Ion' of Euripides. His poetry embodies a philosophy of human life in which he sought to combine art with scientific principles and to weave in one poetic fabric the mythical past with ideal visions yet to be realized by the race. In 1887 he was elected a member of the Academy.

Lecouvreur, lē-koo-vrē, Adrienne, French actress: b. Lamery, Champagne, 5 April 1692; d. Paris 20 March 1730. Arriving at Paris in her tenth year she made her first theatrical venture three years later, and was immediately engaged for the theatre at Lille. For the following ten years she was "on the road" as member of various traveling companies, but in

LE CREUSOT — LEDRU-ROLLIN

1717 was called to the ‘Comédie Française,’ and made her début as Electra in Crebillon’s tragedy. Her simple and natural impersonation made a deep impression on the most fastidious of audiences, and from that time she played the rôle of most of the heroines in Corneille and Racine with such success that she was welcomed into the most aristocratic circles of the city and was drawn into correspondence with some of the most intellectual men and women of the day, among whom was Voltaire. During the last ten years of her life she counted among her admirers Maurice of Saxony, Voltaire and Lord Peterborough. She perished by poison administered by the Duchesse de Bouillon, a jealous rival. This dénouement is the subject of the play ‘Adrienne Lecouvreur,’ by Scribe and Legouvé. Consult: Mouval, ‘*Lettres d’Adrienne Lecouvreur*’ (1892).

Le Creusot, France. See **CREUSOT, LE**.

Lec’tern, or **Lettern**, the reading-desk or stand on which the larger books used in the services of a church are placed. The most ancient lecterns were made of wood, and elaborately carved. Modern ones have been made of marble or brass, very ornamental in design and of excellent execution. They are sometimes made in the form of an eagle, the outspread wings of which form the support for the volume.

Lectionary, lēk’shōn-ā-rī (Lat. *lectionarium*) originally, a service-book of the church of the Middle Ages, so termed as it contained the lessons (*lectiones*) or passages of Scriptures read in the church service. The Roman Catholic Lectionary contained the epistles and gospels of the Roman missal, sometimes also all the lessons of the various services in the church, in which case it was termed the Plenarium. The most ancient known, the Gallican Lectionary, is believed to represent the rite of the ancient Gallican Church. It was published from a manuscript of the monastery of Luxeuil in 1685, by Mabillon (q.v.), who attributed it to the 7th century. It was written in Merovingian characters, it names the festival of St. Geneviève, and assigns three lessons to each mass, in accordance with the ancient Gallican liturgy.

In the Greek Church the lectionaries consist of lessons from the Gospels, from the Acts and Epistles. The Greek lectionary is called *Synaxarion* (συναξάριον), and the oldest synaxarion extant is that prefixed to the Codex Cyprus (K), a manuscript of the New Testament which belongs to the 8th century.

The lectionary or calendar of the English Book of Common Prayer was first published in 1559, and contained two lessons, one from the Old Testament and one from the New for daily morning and evening prayer, and special lessons for Sundays and holidays. This lectionary was adopted by the Protestant Episcopal Church of the United States in 1789, but in 1833 the General Convention changed it by revision into the form which it now bears. In accordance with this assignment the Old Testament is appointed to be read through in the course of public worship once a year; the New Testament being read three times in the same period.

Lectister’niūm, among the ancient Romans, a sacrifice of the nature of a feast offered to the gods, an evident survival of the idea com-

mon in early stages of religious development that divinities actually partook of the offerings presented to them. On occasions of extraordinary solemnity, or in times of public calamity, the Greeks and Romans placed tables with food before images of the gods reclining on couches. According to Livy the first Roman lectisternium took place 354 B.C., when a terrible plague affected the cattle. These sacrificial feasts were of two kinds—ordinary, occurring almost daily, and extraordinary, occurring at intervals, and lasting from three to eight days, or longer.

Lector (reader), a minister of the church who reads the Bible, and other writings of a religious character, to the people. The order of lectors is the second of the minor orders in the Roman Catholic, the first in the Greek Church. The office is now merely looked upon as one of the steps to the priesthood, and only in the office for Good Friday does the missal recognize the functions of the lector. Lectors were consecrated by prayers and sometimes by laying on of the hands for this office; the candidate must have completed the seventh year of his age. They are mentioned by Justin Martyr in the 2d century, and appear to have been proper officers of the church in the 3d century. The orders in the Roman Catholic Church are bishop, priest, deacon, sub-deacon, acolyte, exorcist, reader, ostiarius or door-keeper. See ORDERS, HOLY.

Leda, lē’dā, in Greek mythology, the wife of the Spartan king Tyndareus. In order to enjoy her, Zeus changed himself into a swan, in which form he is represented with her in a picture from Herculaneum. By him she had Pollux and Helen, and by Tyndareus, Castor and Clytemnestra.

Leleganck, lēd-ē-gānk’, Karel Lodewyk, Flemish poet: b. Eecloo 9 Nov. 1805; d. Ghent 19 March 1847. He is one of the most popular of Flemish writers. His first collection of poems was ‘Flowers of my Springtide’ (1839). His poem on ‘The Three Sister Cities’—that is, Ghent, Bruges, Antwerp—is considered his finest production.

Ledochowski, Miecislas Halka, mē-ā-kēs-lās hāl’kā led-ō-hōv’skē, Polish Roman Catholic ecclesiastic: b. Galicia 29 Oct. 1822; d. Switzerland 28 July 1894. He studied theology and subsequently entered the papal diplomatic service and became papal auditor successively at Madrid, Lisbon, Rio de Janeiro, and Santiago de Chile. In 1861 he was appointed Archbishop of Thebes, while his appointment to the archbishopric of Gnesen and Posen in 1866 constituted him primate *ex officio* of Poland. He actively opposed the Prussian May laws by which Bismarck sought to subject the Roman Catholic Church in Germany to state control. In consequence of his opposition, his property was confiscated and himself imprisoned in 1873 for two years. He was made cardinal 15 March 1875, and in 1892 general prefect of the propaganda.

Ledru-Rollin, lē-drü-rȫl-lā̄, Alexandre Auguste, French political agitator: b. near Paris, France, 2 Feb. 1807; d. Fontenay-aux-Roses, France, 31 Dec. 1874. Admitted to the bar in 1830, he became prominent in the defense of Republican journalists and men of similar views in the reign of Louis Philippe, and later as a democratic agitator and leader of the work-

LEDUM OIL—LEE

ingmen's party. On the outbreak of the revolution of 1848 he became a member of the provisional government as minister of the interior, and in May was one of the five in whose hands the Constituent Assembly placed the interim government. But he offended everyone by his arbitrary conduct, and resigned. He was a candidate for the presidency against Louis Napoleon in the following December, but was ignominiously beaten. An unsuccessful attempt to provoke an insurrection against his rival put an end to his influence, and for the next 20 years he lived alternately in London and Brussels, being amnestyed only in 1870. After his return to France he was elected to the Assembly in 1871, and again in 1874.

Le'dum Oil. See LABRADOR TEA.

Led'yard, John, American traveler: b. Groton, Conn., 1751; d. Cairo, Egypt, 17 Jan. 1789. He entered Dartmouth College in 1772, with a view of fitting himself for missionary duty among the Indians. The restraints of this mode of life proving irksome, he absented himself at one time from college for several months, during which he visited the Indians of the Six Nations; and, finally abandoning the idea of becoming a missionary, he embarked on the Connecticut River in a canoe of his own fashioning, and floated down to Hartford. After a brief experience as a theological student, he shipped at New London as a common sailor in a vessel bound for the Mediterranean, and at Gibraltar enlisted in a British regiment, but was discharged at the request of his captain. He accompanied Captain Cook on his third voyage round the world, 1776-80, and of this voyage he kept a private journal, which in accordance with a general order of the government was taken from him on the return of the expedition to England. Subsequently he wrote out from recollection, assisted by a brief sketch issued under the sanction of the admiralty, an account of the expedition, published in 1783. During the two years succeeding his return to England he remained in the British naval service, but steadily refused to take arms against his native country. In December 1782, he found means to escape. He intended to journey through northern Europe and Asia and after surmounting many obstacles arrived at Irkutsk, where on 24 Feb. 1788 he was arrested by order of the Empress Catherine, conducted with all speed to the frontiers of Poland, and there dismissed, with an intimation that he would be hanged if he re-entered Russia. Ledyard found his way back to London in the spring, and was cordially received by Sir Joseph Banks and others who had befriended him. Undaunted by previous adversities, he eagerly accepted an offer to undertake an expedition into the interior of Africa; and when asked how soon he would be ready to set out, replied: "To-morrow morning." He departed from England in the latter part of June, intending to cross the African continent in a westerly direction from Sennaar, and had proceeded as far as Cairo, when he died. For capacity of endurance, resolution, and physical vigor, he was one of the most remarkable of modern travelers. Many extracts from his journals and his private correspondence with Jefferson and others are given in Spark's memoir of him.

Ledyard, William, American soldier: b. Groton, Conn., about 1750; d. Fort Griswold, Conn., 7 Sept. 1781. He held the commission of colonel in the militia of Connecticut, and during the marauding expedition of Arnold in September 1781, was in command of Forts Trumbull and Griswold, which protected New London. He refused a demand for the surrender of Fort Griswold, and resisted for nearly an hour the attack of a British force numbering 800 men. The command of the attacking force devolved upon Major Bromfield, a Tory, who effected an entrance into the fort after nearly 200 of his men had been disabled, including 48 killed, the Americans having lost about a dozen killed. To Bromfield's inquiry: "Who commands this garrison?" Ledyard replied: "I did, sir, but you do now," at the same time handing him his sword. Bromfield immediately plunged it through the body of Ledyard, killing him upon the spot. A massacre of the Americans ensued, which was not ended until more than 100 of them were killed and wounded. A monument has been erected near the spot to commemorate this event.

Lee, Agnes Rand, American writer: b. Chicago. She has published 'The Round Rabbit,' a juvenile, and a translation of 'The Poems of Theophile Gautier' (1903).

Lee, Albert, American author and editor: b. New Orleans 11 May 1868. He was graduated from Yale in 1891, having during his senior year edited the 'Yale Literary Magazine.' In 1891-4, he was on the editorial staff of the New York Sun; in 1895 became editor of 'Harper's Round Table'; and in 1899 was for a short time associate editor of 'McClure's Magazine,' becoming managing editor of 'Harper's Weekly' in the same year. In 1901-3 he was associate editor of 'Collier's Weekly,' taking the position of managing editor in January 1903. He has written 'Tommy Tiddies' (1896); 'Track Athletics in Detail' (1897); 'The Knave of Hearts' (1897); 'Four for a Fortune' (1898); 'He, She, and They' (1899).

Lee, Alfred, American Protestant Episcopal bishop: b. Cambridge, Mass., 9 Sept. 1807; d. Wilmington, Del. 12 April 1887. He was graduated at Harvard in 1827, and after studying law practised for three years in New London, Conn. Feeling, however, that his vocation was elsewhere he was admitted to the General Theological Seminary, where he was graduated in 1837. He was elected rector of Calvary Church, Rockdale, Pa. (1838), but on being consecrated first bishop of Delaware in 1841, took charge of Saint Andrew's, Wilmington, the following year. He was a member of the American Committee for Revision of the New Testament (1881) and presiding bishop (1884-7). He is the author of 'Life of Saint Peter' (1852); 'Life of Saint John' (1854); 'A Treatise on Baptism' (1854); 'Harbinger of Christ' (1857); Co-operative Revision of the New Testament' (1881); etc.

Lee, Ann, foundress of the Society of Shakers in America: b. Manchester, England, 29 Feb. 1736; d. Watervliet, N. Y., 8 Sept. 1784. She was the daughter of a blacksmith and uneducated, and in 1758 joined the Shakers, who had seceded from the Society of Friends. In 1762 she was married to a blacksmith named Standerin, or Stanley. She believed herself in-

LEE

spired, and in 1770 was imprisoned for preaching the new doctrine of celibacy. In 1774 she emigrated to America and founded at Watervliet two American Societies of Shakers. By her adherents she was called "Mother Ann." See SHAKERS.

Lee, Arthur, American diplomatist: b. Stratford, Westmoreland County, Va., 21 Dec. 1740; d. Urbana, Middlesex County, Va., 12 Dec. 1792. He was educated at the University of Edinburgh; entered the practice of medicine at Williamsburg, Va.; studied law in the Temple, London (1766-70); practised in England in 1770-6; closely observed colonial questions; was a member of the society known as "The Supporters of the Bill of Rights," by which ministerial measures were discussed; and in 1770 was appointed associate of Franklin as London agent of Massachusetts colony. When Congress appointed Franklin, Jay, and Dickinson a committee to correspond with friends of the colonies in other parts of the world, Lee became secret agent in London of the committee; and in 1776 he was chosen by Congress joint commissioner with Franklin and Deane to obtain a treaty of alliance with France. In 1777 he despatched special missions to the governments of Spain and Prussia; in 1778 became commissioner to Spain; but in 1779 was recalled owing to his disagreements with Franklin and Deane. He was a representative in the Virginia general assembly in 1781; a delegate to the Continental Congress in 1781-4; and a member of the board of treasury in 1784-9. He opposed the adoption of a Federal constitution. Consult R. H. Lee, 'Life of Arthur Lee' (1829).

Lee, Charles, American soldier: b. Dernhall, Cheshire, England, 1731; d. Philadelphia 2 Oct. 1782. In 1751 he entered the English army as lieutenant of the 44th, which he accompanied to America in 1754, and with which he was present at Braddock's defeat on the Monongahela (9 July 1755). He was wounded in Abercrombie's attack on Ticonderoga (1 July 1758), took part in the capture of Montreal in 1760, and was promoted major in 1761. He served in Burgoyne's division in Portugal in 1762, and was for a time busy with a scheme for establishing in America two colonies, one on the Ohio, the other on the Illinois, to be recruited from Switzerland and Germany as well as New England. In 1764 he went to Poland, there was appointed to the staff of King Stanislaus Augustus, in 1766 accompanied the Polish embassy to Turkey, in 1769 as a major-general in the Polish army fought in a campaign against the Turks, and having called his superior officers fools, left the service and returned to England. He was made lieutenant-colonel on half-pay in 1772, but was further unrecognized by the British government, and in disappointment came to America 10 Nov. 1773, and by skilful display of what military knowledge he possessed attracted the attention of the Continental Congress, then eager to obtain competent leaders for the Revolutionary army. His career thenceforth was perhaps the strangest in the annals of the Revolution. He wished to become commander-in-chief of the American forces, but accepted the appointment as second of the major-generals, Artemas Ward (q.v.) being the first. To inspire public con-

fidence he purchased for £5,000 Virginia currency (about £3,000 sterling), an estate in Berkeley County, Va.; but he did not assume his rank until guaranteed by Congress pecuniary indemnity for possible losses incurred in so doing. He undeservedly received popular credit for Moultrie's successful defense of Charleston, S. C. (28 June 1776), and was called the "Hero of Charleston." In 1776 he became first major-general upon the resignation of Ward. He failed to obey when ordered by Washington to cross the Hudson from Westchester County with his 7,000 troops and join the latter in New Jersey; but when Washington was compelled to fall back on Princeton (2 Dec. 1776), crossed the river to Morristown and encamped there with 4,000 troops. Gates marched from Ticonderoga with seven regiments for Washington's aid, but Lee diverted three of the regiments to Morristown. Washington crossed the Delaware into Pennsylvania, and Lee diligently spread reports of the commander-in-chief's incapacity and planned a flank movement upon the British army whose success he intended should secure his own appointment to replace Washington. He was, however, captured at Baskingridge (13 Dec. 1775), and imprisoned at New York, where he deserted the American cause, and designed a plan for the subjugation of the American colonies, the original draft of which was found among the private papers of the Howes in 1857. He was exchanged in 1778, and re-entered the American service for reasons not fully known; but his insubordination at Monmouth (28 June 1778) nearly lost the day, and he was suspended from command for one year. A subsequent disrespectful letter to Congress caused his dismissal from the army. His treasonable correspondence with the British authorities was not discovered till many years after. He wrote 'Strictures on a Friendly Address to all Reasonable Americans' (1774) in reply to Dr. Myles Cooper (q.v.); and made a foolish claim to be the author of the "Junius" letters. Consult the 'Memoirs,' edited from his papers by Langworthy (1792); and Moore, 'The Treason of Charles Lee' (1858).

Lee, Charles, American cabinet officer: b. Leesylvania, Va., 1758; d. Fauquier County, Va., 24 June 1815. He was a brother of Henry Lee, soldier (q.v.). He was graduated from the College of New Jersey in 1775; studied law in the office of Jared Ingersoll at Philadelphia; practised in Westmoreland County, Va.; and sat in the Virginia assembly. On 10 Dec. 1795 he was appointed by Washington attorney-general of the United States, and this office he filled until the last month of Adams' administration (1801). He declined an appointment by Jefferson as chief justice of the United States circuit court for the 4th circuit.

Lee, Eliza Buckminster, American prose writer: b. Portsmouth, N. H., 1794; d. Brookline, Mass., 22 June 1864. She was married to Thomas Lee of Boston, where the greater part of her life was spent. She was a popular author in her day and among her books are 'Sketches of New England Life' (1837); 'Delusion' (1839); a translation from the German of the 'Life of Jean Paul Richter' (1842); 'Naomi; or, Boston Two Hundred Years Ago' (1848); 'Parthenia; or, The Last Days of

LEE

Paganism' (1858); and a translation of Berthold Auerbach's 'Barefoot Maiden' (1860).

Lee, Fitzhugh, American soldier and diplomatist: b. Clermont, Fairfax County, Va., 19 Nov. 1835. He was the nephew of Robert E. Lee (q.v.). Appointed as cadet at large to West Point by President Fillmore, he entered the Academy at 16 and was graduated in 1856, being at the head of his class in horsemanship, and receiving an appointment to the famous Second Cavalry of which A. S. Johnston was colonel and R. E. Lee was lieutenant-colonel. After serving for a year at Carlisle Barracks as cavalry instructor of recruits, he reported to his regiment on the frontier of Texas and was greatly distinguished in several fights with the Indians, being mentioned in the official reports for skill and gallantry. In a fight with the Comanches, 13 May 1859, he was so severely wounded, being pierced through the lungs with an arrow, that the surgeons despaired of his life, but he recovered and joined his command, and led a part of his company in January 1860, in a very notable and successful fight with the Indians, in which he greatly distinguished himself in a single combat with an Indian chief. In November 1860 he was ordered to West Point as instructor of cavalry tactics. When Virginia seceded from the Union he promptly resigned his commission and tendered his services to his native State. He served for a time on the staff of General R. S. Ewell, and in September 1861 he became lieutenant-colonel, and in April 1862 colonel of the 1st Virginia cavalry. Henceforth he was intimately connected with Stuart's cavalry and won constant reputation for dash, daring, and intelligent execution of duty. After the battles around Richmond he was made brigadier-general, his brigade consisting of the 1st, 3d, 4th, 5th, and 9th Virginia cavalry, and a battery of horse artillery. In the campaign against Pope and the Maryland campaign the cavalry rendered most important service, and Gen. Lee did his full duty in these operations. When General Robert Lee withdrew from Sharpsburg, Fitzhugh Lee's brigade relieved the pickets and held the lines till the army had crossed the Potomac. On 17 March 1863 Averell's division of 3,000 cavalry crossed the river at Beverly's Ford, and attacked him; though he could only put 800 troopers in the saddle, he successfully resisted Averell, and after one of the most hotly contested cavalry battles of the war drove him back across the river. In the Chancellorsville movement he protected Jackson's flank, and made a very important reconnaissance by which he located the flank and rear of the enemy, and enabled Jackson to attack it to the best advantage. In the autumn of 1863 he was made major-general, and given command of a division of cavalry. In the campaign of 1864 he rendered important service, holding in check the advance of Grant's army until General R. E. Lee's infantry could occupy Spotsylvania, repelling Sherman's raid on Richmond, defeating Sheridan at Trevilians and Samaria Church, routing Wilson at Reams Station, and operating with Early in the Valley, being severely wounded at the battle of Winchester. When Hampton was sent south Lee was given the command of the entire cavalry corps of the army of northern Virginia, con-

ducted the retreat to Appomattox, was one of the council of war whom Robert Lee consulted, and one of the leaders in the last charge of the army of northern Virginia. He "accepted the situation" after the surrender, and went to work on his farm at Richland. From 1886 to 1890 he was governor of Virginia. In 1896 he was appointed consul-general to Cuba, in which position he kept the State Department thoroughly informed of the Spanish policy during the rebellion, and vigorously upheld the rights and interests of the United States; after the destruction of the Maine he did much to prevent the premature outbreak of war with Spain, but when war was inevitable he was recalled. In May 1898 he was appointed major-general of United States volunteers, and assigned to the command of the 7th army corps. At the close of the war he was made military governor of the province of Havana, and later was given the command of the department of the Missouri.

J. W. JONES, D.D.,
President Southern Historical Society.

Lee, Francis Bazley, American lawyer and historical writer: b. Philadelphia 3 Jan. 1869. He was educated at the State Model School in Trenton, N. J., and was graduated from the Wharton School of Political Economy in the University of Pennsylvania in 1890. He was admitted to the New Jersey bar in 1893 and has since practised his profession in Trenton. In addition to various historical monographs relating to New Jersey, he is the author and editor-in-chief of 'New Jersey as a Colony and a State.'

Lee, Francis Lightfoot, American patriot: b. Stratford, Westmoreland County, Va., 14 Oct. 1734; d. Richmond County, Va., 3 April 1797. He was elected to the Virginia house of burgesses for Loudoun County in 1765, and later represented Richmond County in that assembly. He signed the Westmoreland declaration against the Stamp Act (1765), and on 15 Aug. 1775 became a member of the Continental Congress, where he served until the spring of 1779. On 4 July 1776 he was one of the 56 signers of the Declaration of Independence. He also was a member of the committee that prepared the articles of confederation, and was prominent in debate, particularly on the questions of the Newfoundland fisheries and the navigation of the Mississippi. After his retirement from Congress he served briefly in the Virginia legislature. Consult Sanderson, 'Lives of the Signers,' Vol. IX. (1827).

Lee, Gerald Stanley, American Congregational clergyman and author: b. Brockton, Mass., 4 Oct. 1861. He was graduated from Middlebury College, Vt., in 1885, and from Yale Divinity School in 1888. He has lectured on literature and the arts, and is the author of 'About an Old New England Church' (1893); 'The Shadow Christ' (1896); 'The Lost Art of Reading' (1902); 'The Confessions of an Unscientific Mind' (1902).

Lee, Guy Carleton, American educator and author. He was graduated from Dickinson College, Pa., where he was for a time professor of history. He has since filled other educational posts and has been literary editor of the Baltimore *Sun* from 1901. He is the author of:

LEE

'Hincmar: An Introduction to the Study of the Church in the 9th Century' (1898); 'Principles of Public Speaking' (1899); 'Historical Jurisprudence' (1900); 'Source Book of English History' (1900); 'A History of England' (1901).

Lee, Mrs. Hannah Farnham Sawyer, American novelist and miscellaneous writer: b. Newburyport, Mass., 1780; d. Boston 27 Dec. 1865. She was married to G. G. Lee of Boston. Her works, several of which exerted considerable influence during the second quarter of the 19th century, are: 'Grace Seymour' (1835); 'Three Experiments in Living' (1838); 'Elinor Fulton,' a sequel to the preceding; 'Rich Enough'; 'The Huguenots in France and America' (1842); 'Stories from Life' (1849); 'Memoir of Pierre Toussaint' (1853); 'History of Sculpture and Sculptors'; etc.

Lee, Harriet, sister of Sophia Lee (q.v.): b. London 1756; d. Clifton 1 Aug. 1851. In 1786 she published the 'Errors of Innocence,' a novel succeeded by several others now forgotten. In 1797-1805 appeared her 'Canterbury Tales,' 8 of the 10 tales of which were her own, the others being by her sister Sophia. They enjoyed a great popularity in the early part of the 19th century, and a new edition was published in New York in 1856-7. One of the most remarkable is 'The German's Tale-Krutzner,' from which Lord Byron borrowed not merely the plot and the machinery down to the most trivial incidents, but in some instances the language, of his 'Werner.' She also wrote two dramas, the 'New Peerage' and the 'Three Strangers.'

Lee, Henry, American soldier: b. Leesylvania, Westmoreland County, Va., 29 Jan. 1756; d. Cumberland Island, Ga., 25 March 1818. He was graduated from the College of New Jersey in 1774; in 1775 became a captain in Col. Theodoric Bland's legion of Virginia cavalry; and in September 1777 joined Washington's army in Pennsylvania. Promoted major for services in battle (January 1778), he was given command of a partisan corps consisting of two troops of horse, and later increased by a third troop and an infantry company. This corps, which was employed in the annoyance of the British march and camp, was known as 'Lee's legion,' and its commander as 'Light Horse Harry.' On 19 Aug. 1779 Lee surprised and captured the British post at Paulus Hook (q.v.), N. J. For this achievement, which is regarded as one of the most brilliant exploits of the Revolution, Congress voted him a gold medal. He was promoted lieutenant-colonel, and in the autumn of 1780 was sent to South Carolina to join Greene's army. He covered the American retreat through North Carolina (February 1781), and was involved in some smart skirmishes with Tarleton's dragoons. After Greene had crossed into Virginia, Lee remained in North Carolina to harass the enemy, and, although he could not surprise Tarleton, did defeat 400 loyalists under Col. Pyle. He outfought Tarleton at Guilford Court House (15 March 1781), and with Marion, by cutting Rawdon's line of communication, compelled that officer to abandon Camden (10 May 1781). He took Augusta, Ga. (5 June 1781), and having rejoined Greene, fought with distinction at Eutaw Springs (8 Sept. 1781), and captured some of Rawdon's rear-guard in the

British retreat. After having been present at Yorktown, he shortly resigned his commission. In 1785-8 he was a Virginia delegate to the Continental Congress; in 1788 was a member of the Virginia convention for the ratification of the Federal constitution; in 1789-91 sat in the general assembly of the State; and in 1792-5 was governor. In 1794 he was appointed by Washington to command the 15,000 troops sent to suppress the 'Whiskey Insurrection' (q.v.) in western Pennsylvania. After service as a representative in the Sixth Congress (1799-1801), he withdrew from public life. In his 'Funeral Oration upon President Washington,' pronounced in 1799 before both houses of Congress, occurs the since famous phrase, 'First in war, first in peace, first in the hearts of his fellow-citizens.' He wrote 'Memoirs of the War in the Southern Department of the United States' (1812), published in revision with a memoir by his son R. E. Lee (q.v.) in 1869.

Lee, Henry Washington, American Protestant Episcopal bishop: b. Hamden, Conn., 26 July 1815; d. Davenport, Iowa, 26 Sept. 1874. He was graduated from Trinity College, Hartford, in 1835; studied theology, and received deacon's orders in 1838. In 1840-8 he was rector at Springfield, Mass., and in the latter year took charge of St. Luke's Church in Rochester, N. Y. In 1854 he was made bishop of Iowa, holding the position till his death; he was one of the founders of Griswold College at Davenport, and was instrumental in obtaining an endowment for his diocese and the erection of the cathedral. He published 'Manual of Family Prayers,' and a number of sermons and addresses; also 'Prayers for Children' and other books for young people.

Lee, James Wideman, American Methodist clergyman: b. Rockbridge, Ga., 28 Nov. 1849. He was graduated from Emory College, Ga., in 1875; in 1876 was ordained to the ministry of the Methodist Episcopal Church South, and held Georgia pastorates in Carrollton, Dalton, Rome, and Atlanta. In 1893 he went to St. Louis as pastor of St. John's Church; was presiding elder in St. Louis from 1897 to 1901, when he returned to his pastorate at St. John's. In 1894 he was the head of an expedition to Palestine to secure material for the 'Earthly Footsteps of Christ and His Apostles,' which he published in 1895 (with J. H. Vincent, q.v.). He has also written: 'The Making of a Man' (1892), translated into Japanese and Chinese; 'Henry W. Grady, Editor, Orator and Man' (1896); 'History of Methodism' (1900); and has edited and illustrated the 'Self Interpreting Bible.'

Lee, Jennette Barbour Perry, American novelist: b. Bristol, Conn., 10 Nov. 1860. She was graduated from Smith College, Mass., in 1886, was professor of English in the College for Women at Western Reserve University 1893-6, and in the year last named was married to Rev. G. S. Lee (q.v.). She has published: 'Kate Wetherell' (1900); 'A Pillar of Salt' (1901); 'The Son of a Fiddler' (1902).

Lee, Jesse, American Methodist clergyman: b. Prince Edward County, Virginia, 1758; d. September 1816. He was admitted to the Conference as a preacher among the Methodists in 1783, and was chosen as a friend and traveling

LEE

companion by Francis Asbury. His writings have been the basis of much of the history of early Methodism in America. In 1789 he traveled over New England and preached Methodism from Connecticut to Maine. He formed the first Methodist congregation in New England at Stratfield, Conn., 26 Sept. 1787. In 1792 he preached in Massachusetts, and gathered the first class at Boston 13 July 1792. He was chaplain to Congress during six successive terms. He is known in New England as "The Apostle of Methodism." He wrote 'A History of Methodism in America' (1807). Consult: Lee, 'Life and Times of Jesse Lee', (1848).

Lee, John Doyle. See MOUNTAIN MEADOW MASSACRE.

Lee, Luther, American Methodist clergyman: b. Schoharie, N. Y., 30 Nov. 1800; d. Flint, Mich., 13 Dec. 1889. He entered the Genesee Conference in 1827, became an itinerant preacher and a temperance and anti-slavery lecturer, and was several times mobbed on account of his abolitionist sentiments. From 1843 to 1867 he was a member of the Wesleyan body, having as a Wesleyan clergyman been president in 1853 of Michigan Union College at Leoni, and pastor of churches at Syracuse and elsewhere, but in 1867 returned to the Methodist Episcopal denomination. He was the author of 'Universalism Examined and Exposed' (1836); 'The Immortality of the Soul' (1850); 'Slavery Examined in the Light of the Bible' (1855); 'Elements of Theology' (1856); etc.

Lee, Margaret, American novelist: b. New York 27 Nov. 1841. Among her numerous fictions may be cited 'Lorimer and Wife' (1881); 'Divorce' (1882); 'One Touch of Nature' (1892).

Lee, Mary Catherine Jenkins, American novelist: b. New Bedford, Mass. She has published: 'A Quaker Girl of Nantucket' (1889); 'In the Cheering Up Business' (1891); 'A Soulless Singer' (1895).

Lee, Nathaniel, English dramatic poet: b. Hatfield about 1653; d. London 1692. He was educated at Cambridge, turned his attention to the drama, and in 1675 produced his tragedy of 'Nero,' and from that time to 1681 produced a tragedy yearly. From 1684 to 1688 he was confined in Bethlehem Hospital on account of insanity, and after his discharge wrote two more tragedies. He is the author of 11 plays, all of which were acted with applause; but his natural fire and pathos were buried in a torrent of words, and clouded by a tendency to turgid and bombastic eloquence. In his play, 'The Rival Queens' (1677), occurs the oft-quoted line:

When Greeks joined Greeks then was the tug of war.

Lee, Richard Henry, American patriot: b. Stratford, Westmoreland County, Va., 20 Jan. 1732; d. Chantilly, Va., 19 June 1794. He was educated in England, but returned in 1752 to Virginia, where he soon became prominent in public affairs, and was elected to the house of burgesses. In 1773 he became a member of the committee of correspondence to communicate with the other colonies, and in 1774 was a delegate from Virginia to the first Continental Congress. There he attracted attention by his eloquence, and drafted the petition to the king. In the second Congress he prepared the address

to the people of Great Britain. Both of these documents are remarkable state papers. On 7 June 1776 he moved "that these united colonies are and of right ought to be free and independent states; that they are absolved from all allegiance to the British crown; and that all connection between them and the states of Great Britain is and ought to be totally dissolved." He was in the Virginia legislature in 1780-4, was elected president of Congress in 1784, in 1786 was again a member of the State legislature, and in 1787 also sat in Congress. Upon the adoption of the Federal Constitution, to which he was opposed, he was elected one of the first two senators from Virginia, and there remained, at first as an anti-Federalist, until his resignation in 1792. He was one of the notable orators of his time. Consult: R. H. Lee (his grandson), 'Life and Correspondence of R. H. Lee' (1825).

Lee, Robert Edward, American soldier: b. Stratford, Westmoreland County, Va., 19 Jan. 1807; d. Lexington, Va., 12 Oct. 1870. He received his secondary education in good private schools in Alexandria, Va., and when he entered West Point, at 18, in 1825, at once took a very high stand, maintained it throughout his course, and was graduated second in his class, without ever receiving a single demerit, a record very rarely attained. He was at once commissioned brevet 2d lieutenant in the engineers, and won high reputation in this important branch of the service. In 1832 he married Mary Custis, daughter of the adopted son of Washington, and thus became proprietor of Arlington on the Potomac, and other estates. In 1836 he was promoted to 1st lieutenant, and in 1838 was made captain. In the Mexican War he made a brilliant record for skill and gallantry as an engineer officer, being brevetted major at Cerro Gordo, 18 April 1847, lieutenant-colonel at Contreras, and Churubusco, and colonel at Chapultepec. General Scott constantly consulted him, acted largely on his advice, and mentioned him repeatedly in his official reports. At the close of the Mexican War he was made a member of the board of engineers of the United States army; 1 Sept. 1852 he was made superintendent of the Academy at West Point, and filled the position so ably and acceptably that there was a general desire to retain him; but in 1855 he was made lieutenant-colonel of the 2d cavalry, and did very efficient service against the Comanches and other Indians on the frontier of Texas. In October 1859 the John Brown raid at Harper's Ferry occurred, and Lee chancing to be at Arlington on furlough was ordered with a body of marines to suppress the revolt, and did so very promptly by storming the engine house in which John Brown and his party had taken refuge, and turning them over to the civil authorities. Soon after he was promoted to a full colonelcy, but the war came on rapidly, and he was soon to close his service in the United States army.

He was an ardent Union man, and hoped against hope that some compromise might be reached. When, however, the war had actually begun, and Virginia had seceded, he did not hesitate long as to the path of duty. President Lincoln sent the elder Blair to him with an offer of the supreme command of the United States

LEE

army, but while treating the offer and the message with all proper respect, he told Mr. Blair very emphatically that he "could not take up arms against his State, his home, and his children." A few days later he sent in his resignation. Having once decided the question he never faltered in his allegiance, or doubted the correctness of his decision. He said to General Wade Hampton, in 1869, as they were discussing the war and its results: "I could have taken no other course without dishonor, and if it were all to be gone over again, I should act in precisely the same manner." Going to Richmond at the request of the Virginia Convention, he was made major-general and commander-in-chief of the Virginia forces, and when Virginia joined the Confederacy he was commissioned in the Confederate service, and was made one of the five full generals. His services in organizing and equipping raw troops, and planning campaigns were very valuable, and the latter part of July 1861 he took command in West Virginia; the campaign failed through the fault of others, and he was severely criticised by the newspapers. He was put in charge of the sea coast defenses in South Carolina and Georgia, and there can be but little doubt that his skill and energy did much to put that department in condition to make the heroic defense afterward made. In February 1862 he was made military adviser to President Davis, and occupied that position till the wounding of General Johnston at Seven Pines, and on 3 June was assigned to the command of the Army of Northern Virginia. Determining not to await McClellan's expected reinforcements General Lee at once began preparations to attack and drive him from the siege of Richmond. Accordingly he summoned "Stonewall" Jackson to his aid, collected all other reinforcements that he could, and on 26 June opened the Seven Days' battles by attacking McClellan's lines on the Chickahominy. The Confederates won several victories, and while they were repulsed at Malvern Hill, where McClellan had made a last stand to save his army, Lee had prepared for a combined attack the next morning, when McClellan retreated that night under the cover of his gunboats at Harrison's landing, 30 miles below Richmond. While McClellan's army was not annihilated, as Lee designed, and as might have been but for the failure of some of his subordinates, yet the siege of Richmond had been raised and McClellan's army was in a demoralized condition. Lee also captured 52 pieces of artillery, small arms, and large quantities of stores of every description. The Government at Washington were now far more solicitous about the safety of Washington than for the capture of Richmond, and Lee by a series of maneuvers brought it to pass that McClellan's troops were all brought to Washington to reinforce General Pope, who had taken command of the Army of Virginia. Lee's campaign against Pope culminated in the battles on the old field of Manassas, where the Confederate commander routed Pope and drove him into the fortifications in front of Washington. (See BULL RUN, SECOND BATTLE OF.) Then followed the Maryland campaign, in which Jackson captured Harper's Ferry with 11,000 prisoners and large quantities of arms and stores. At Sharpsburg (Antietam), 17 Sept. 1862,

Lee resisted every attack of McClellan's well equipped troops, advanced his lines on parts of the field, and remained in battle line 24 hours, though his men were weakened by lack of food, and then learning that McClellan was receiving large reinforcements, withdrew across the Potomac unmolested. (See ANTIETAM, BATTLE OF.) On 7 November orders from Washington relieved McClellan and put Burnside in his place, who tried to "steal a march" and crossed the Rappahannock at Fredericksburg, but Lee divined his purpose and confronted him there. Both sides concentrated for battle and Burnside attacked Lee, who occupied a naturally strong position; the result was that Burnside received a bloody defeat and recrossed the river, where his strong works and heavy artillery rendered him safe from a counter attack from Lee. (See FREDERICKSBURG, BATTLE OF.) In February 1863 Burnside was succeeded by Hooker, whom Lee defeated at Chancellorsville (q.v.). In the Gettysburg campaign of 1863 Winchester was captured by Ewell and at Gettysburg, 1-3 July, Lee fought General Meade, gaining a decided victory the first day, gaining some ground on the second day, and receiving a bloody repulse on the third day. Though he remained in line of battle all day the 4th of July, and then for nine days afterward at Hagerstown, with an impassable river at his back, Meade did not attack, and Lee later retreated into Virginia. In 1864 General Grant had been made commander-in-chief of the United States army and took personal command of the army that was "to crush Lee and capture Richmond." He had under his command about 275,000 men well equipped and provisioned. To meet him Lee had not more than 75,000 men, badly armed, wretchedly equipped and poorly supplied with rations, clothing, ordnance stores, and transportation. And yet in that campaign he outgeneraled Grant, defeated him in every battle from the Wilderness to Petersburg and compelled him to sit down before Petersburg. During the remainder of the summer, fall and winter, Lee had to guard 40 miles of breastwork with a bare skirmish line, and yet meet every move of the enemy to supply his army when the railways not occupied by the enemy were all broken down, to recruit his thin and thinning ranks from a country already stripped of its men, and to witness the starving out of his army—yet all of these and other obstacles were met with a fertility of resource born of the highest order of military genius. In the early part of 1865 he was made commander-in-chief of all the armies of the Confederacy, but it was now too late to accomplish anything against the "overwhelming numbers and resources" against him. Shortly after the opening of the campaign of 1865, Lee determined to unite with Johnston, and strike Sherman before Grant could join him, but the condition of the roads and the lack of proper transportation delayed him until the active movements of Grant forestalled him, and brought the disasters of 1 and 2 April, which forced Lee's retreat and the end at Appomattox on 9 April, when the Army of Northern Virginia surrendered. When Lee rode into Richmond he was cheered by the Federal soldiers; and used his wide influence to pacify the country.

In October 1865 he became president of Washington College (now Washington and Lee

GEN. ROBERT E. LEE.

'LEE—LEE FAMILY

University), Lexington, Va., and under his excellent administration the college was greatly improved and enlarged. His character was marked by modest simplicity and gentleness, by a spirit of self-denial, by want of bitterness toward the North but devotion to the interests of the South, by firmness in carrying out his purpose, and above all by simple, sincere active piety. Virginia has recently selected Lee as one of her two representatives whose statues are to be placed in the rotunda of the Capitol at Washington.

J. W. JONES, D.D.,
President Southern Historical Society.

Lee, Sarah Wallis, English naturalist: b. Colchester, Essex, 10 Sept. 1791; d. Erith, Kent, 22 Sept. 1856. At 22 she was married to T. E. Bowditch, whom she accompanied on a mission of pacification to the Ashantees, and while with him in the Cape Coast Colony collected materials for a work on the aborigines of that country, which appeared in 1825, entitled 'Stories of Strange Lands.' Another work of the same character, entitled 'The African Wanderers' (3d ed. 1854), was equally popular. Her husband died in 1824 and she afterward lived in Paris, where in 1829 she was married to Robert Lee. She published in addition to the works named: 'Elements of Natural History: Zoology'; 'Taxidermy,' long a standard authority; 'Familiar Natural History'; etc.

Lee, Sidney, English author and literary editor: b. London 5 Dec. 1859. He was educated at Balliol College, Oxford, was assistant editor 'Dictionary of National Biography,' Vols. I.-II. (1883-90), joint-editor with Leslie Stephen (q.v.) Vols. XXII.-XXVI. (1890-1), and sole editor Vols. XXVII.-LXIII. (1891-1901), and of its Supplement, Vols. LXIV.-LXVI. (1902). To this work he contributed 820 articles. He is the author of 'A Life of William Shakespeare' (1898); 'A Life of Queen Victoria' (1902). In 1903 he delivered a course of Lowell Institute lectures in Boston, Mass., repeating them in other American cities also. These lectures, revised and somewhat extended, were collected in book form entitled, 'Great Englishmen of the 16th Century' (1904).

Lee, Sophia, English author: b. London May 1750; d. Clifton, near Bristol, 13 March 1824. She was the eldest daughter of John Lee, an actor. She was the author of a comedy entitled 'The Chapter of Accidents,' brought out at Haymarket Theatre in 1780 with great success. The next year her father died, and she removed with her sisters to Bath, where she devoted the profits of her play to the establishment of a young ladies' seminary over which she and her sister Harriett (q.v.) long presided. She wrote two or three novels and contributed 'The Young Lady's Tale,' and 'The Clergyman's Tale' to the 'Canterbury Tales,' published by herself and her sister.

Lee, Stephen Dill, American soldier: b. Charleston, S. C., 22 Sept. 1833. He was gradu-

ated from West Point in 1854; served on the frontiers of Texas, Kansas, and Nebraska; was promoted to the rank of 1st lieutenant in 1856, and served in Florida in 1857. On the secession of South Carolina, he resigned from the United States army, and was made captain of South Carolina volunteers, and gradually rose from this rank to that of lieutenant-general. He was at Seven Pines, at the Seven Days' Battles around Richmond, in the campaign against Pope, and at the second battle of Bull Run. He was placed in command of the forces at Vicksburg, but was succeeded by General Pemberton before the capture of the city by the Federals. After the war he settled at Columbus, Miss., and soon took a prominent part in the affairs of the State. He was elected to the State Senate in 1870, and was a prominent member of the constitutional convention in 1890. In 1880 he was made president of the State Agricultural and Mechanical College at Starkville, holding this position till 1899, when he became commissioner of the Vicksburg National Park.

Lee, Vernon. See *PAGET, VIOLET*.

Lee, William, English inventor: b. Nottinghamshire, England, about 1560; d. Paris, France, about 1610. He was a graduate of Cambridge University and is remembered as the inventor of the stocking frame. He presented a pair of silk stockings, knit by his machine, to Queen Elizabeth in 1598, but the hand-knitters violently opposing the introduction of machinery to do their work, he went to France. Meeting with no better success there he became greatly discouraged, and his death is said to have resulted from his disappointment.

Lee, William, American diplomatic representative: b. Stratford, Va., 1737; d. near Williamsburg, Va., 27 June 1795. He was a brother of Arthur Lee (q.v.), Francis Lightfoot Lee (q.v.), and Richard Henry Lee (q.v.). Prior to the Revolution he was active as a merchant in London; and there he was for a time agent of Virginia colony. In 1777 he became associated with Thomas Morris (q.v.) as superintendent of the commercial affairs of the United States at Nantes, France, and in 1778 was appointed commissioner to Prussia and Austria, but accomplished nothing. A treaty drawn up by him with Neufville, a merchant of Amsterdam, in 1778, and approved by the burgomaster of that city, became the avowed cause of the war declared by Great Britain against Holland. Consult Wharton, 'Revolutionary Diplomatic Correspondence of the United States' (1889).

Lee Family, The, a family of Virginia, some of whose members have been conspicuous in public affairs at almost every stage of American history. Among all the eminent names of the South there is none that outranks this in the number or prominence of those who represent it in the records of the nation. Sprung from a cavalier line of old and distinguished English stock, the Virginia Lees have continued in the New World that order of Old-World aristocracy—an aristocracy of character and culture, of honor and of public service—which has legitimated itself under the broadening conditions of democratic development, and to which, as well as to the plainer but not less masterful middle-class English element that elsewhere en-

LEE-HAMILTON — LEECH

tered into the making of the republic, democracy in the American Commonwealth owes its most essential traits. That Richard Lee who, during the reign of Charles I., brought his large household to Virginia, and himself became the first of this illustrious line in America, brought also to the Northern Neck in Northumberland County, where he settled, an English yeoman's sturdiness raised and enlightened and nowise debilitated by the refinements of gentility. A stout partisan of the Stuart cause, he supported Sir William Berkeley (q.v.) in his resistance to Cromwell's policy, and through this attitude the colonists, threatened by the Protector's fleet, forced its commander into a treaty styling the colony an independent dominion. Lee is said to have joined successfully with Berkeley in having Charles II. proclaimed king in Virginia nearly two years earlier than his final coronation in London. Richard Lee's son Richard and the second Richard's third son, Thomas, were leaders in the colony, Thomas dying just as his governor's commission was made out. By his wife, Hannah Ludwell, he had five sons who became distinguished for public and patriotic acts. Of these, Richard Henry Lee (q.v.), by reason of the diversity and singular efficiency of his services, rendered for many years before the Revolution, during that struggle, and for ten years afterward, to Virginia and all the colonies and later States, stands among the pre-eminent figures of his day. The steps preliminary to the Declaration of Independence can never be recalled without remembrance of him as mover of the resolutions which led to its adoption in the Continental Congress. The address to the people of Great Britain, which he wrote, is perhaps surpassed in weight and loftiness of spirit by no American state paper. His brother, Francis Lightfoot Lee (q.v.) not only was one of the signers of the Declaration, but also made liberal sacrifices for the patriot cause, all the more to be remembered to his honor when it is considered that by temper and education he was fitted rather for the occupations of a student, and for social elegancies, than for the turmoil of politics and the tragedies of war. Arthur Lee (q.v.), youngest son of Thomas, was educated in two professions, medicine and law, and distinguished himself by public services both at home and abroad. As representative of the colonies in Europe during the Revolution, he displayed abilities as a man of learning, versatility, and political sagacity, which he applied in ways highly useful to his country in critical times. William Lee (q.v.), another of the sons of Thomas, also represented the United States in Europe at that period, with less distinction than others of this family attained, but not without some exhibition of their unusual qualities. The fame of Henry Lee (q.v.), the "Light Horse Harry" of the Revolution, unique in several respects, is enduring by reason of his political and military services, while his name is endeared to the American people for his noble eulogy of Washington. As first cousin of Richard Henry and of Arthur Lee, his rights are as valid as theirs in the name to which he adds a lustre in return for that it sheds on him. His son Robert Edward Lee (q.v.) not only stands as a connector of the two great epochs of his country's history—the Revolutionary period and that of the Civil War—but in his life and

deeds, too recent to call for special reference here, he worthily perpetuated the fame of the great family whose name he bore, whose blood, whose spirit, whose traditions he inherited. His nephew, Fitzhugh Lee (q.v.), whose name may fittingly close this sketch, still represents in vigorous manhood the typical family stock; and to the varied honors of his predecessors he not only adds his own well-won fame, but joins to that a signal distinction, which he shares with fellow soldiers of the South, as one of those Americans who, in civil and in military life, have proved themselves efficient factors in the final restoration of the Union.

JOHN H. CLIFFORD,

Editorial Staff, "Encyclopedia Americana."

Lee-Hamilton, Eugene, English poet: b. London January 1845. He was educated at Oxford, and entered the diplomatic service in 1869, resigning in 1875. He was for many years an invalid, obliged to maintain a recumbent posture continually. Among his published works are: 'Poems and Transcripts' (1878); 'The New Medusa' (1882); 'Imaginary Sonnets' (1888); 'The Fountains of Youth' (1891). He is a half-brother of Violet Paget (q.v.), "Vernon Lee," and married in 1898 the novelist Annie E. Holdsworth (q.v.).

Lee, Mass., town, in Berkshire County; on the Housatonic River, and on the New York, N. H. & H. railroad; about 33 miles northwest of Holyoke, and 13 miles south of Pittsfield. The town includes the villages of South and East Lee. Lee is situated in an agricultural region; but the country is traversed by the southern spurs of the Green Mountains, known as the "Berkshire Hills" in this region. The delightful climate and beautiful scenery make Lee and vicinity favorite summer resorts. The town was settled in 1760 and incorporated in 1777. A fine white marble found in the town is much used for building purposes. The principal manufactures are paper and dairy products. The government of the town is administered by a town meeting or by officials elected at the annual town meeting. Pop. (1900) 3,506. Consult: Hyde and Hyde, 'Centennial History of Lee.'

Lee-board. See CENTRE-BOARD.

Lee-Metford Rifle, a military weapon manufactured for the use of the United States navy. It is a gun discharging a steel-jacketed bullet with smokeless powder. The velocity of the bullet is 2,460 feet per second, and the penetration, at the regulation range of 15 feet, is 62 pine boards each seven eighths of an inch in thickness. The pressure on the gun when fired is 60,000 pounds to the square inch. The rifle will kill at over a mile.

Leech, John, English illustrator: b. London 29 Aug. 1817; d. there 29 Oct. 1864. He studied at the Charterhouse School nine years, where Thackeray was his school-fellow; began the study of medicine at St. Bartholomew's Hospital; but soon he gave up his medical studies, and began making drawings. The first of his important works were the illustrations to the 'Ingoldsby Legends.' He joined the staff of 'Punch' in 1841. In that field he worked with pre-eminent success, supplying weekly pictures of all sections of English life—scenes of field and forest, of the busy streets, of the rustic cottage and ale-house, and the elegant city

LEECH LAKE — LEEDS

dwelling and club; the huntsman, the swell, the injured paterfamilias; the fast young lady and her grave portly mother; the housemaid and her follower, etc., all thrown off with remarkable precision, and showing a steady growth in artistic power. He was buried beside Thackeray in Kensal Green Cemetery. His designs for 'Punch' have nearly all been published separately as 'Pictures of Life and Character' and as 'Pencillings from Punch.' He also executed the Illustrations for 'The Comic History of England,' 'The Comic History of Rome,' and various other books. Consult: Brown, 'John Leech' (1882); Everitt, 'English Caricaturists' (1886); 'Life,' by Frith (1891).

Leech Lake, a body of water in Cass County, Minn.; the largest of the lakes which constitute the head-waters of the Mississippi River. It is about 1,300 feet above the level of the sea; 24 miles long and 15 miles wide. The short stream, which is the direct outlet of the lake and flows into the Mississippi, is called Leech Lake River. On the south and east shores is the Leech Lake Indian Reservation. The country round is well wooded and fish and game are plentiful.

Leeches, highly specialized *Annelida* constituting the order *Hirudinea* or *Discophora*. They are distinguished from most other annelids by the nearly complete obliteration of the coelom or body-cavity, owing to the development of parenchymatous connective tissue, muscles, etc., the presence of an anterior or oral sucker and a posterior or subanal sucker, and by the absence of setæ, except in *Acanthobdella*. In all leeches which have been carefully studied there are exactly 34 segments or somites, each represented by a ganglion in the central nervous system, and being of smaller size and simpler structure toward the ends than in the middle of the body, where each is divided into from 2 to 12 rings, one of which, sometimes regarded as the first sometimes as the middle ring, bears metamerick eye-like sense organs. Most leeches are temporary parasites, a few nearly permanent parasites; the rest are predatory hunters or scavengers, or they may change from one mode of life to another. They are marine, fresh-water, or terrestrial. The first class is most abundant, both in individuals and species, in cold seas, the second is both temperate and tropical, and the third is confined to warm regions. Four families are distinguished: the *Ichthyobdellidae* or fish-leeches, the *Glossiphonidae* or tortoise and snail leeches, the *Herpobdellidae*, or worm-leeches, and the *Hirudinidae*, or jawed leeches. The first two families possess a long protrusible proboscis and are much more closely allied than the *Herpobdellidae* and *Hirudinidae*, which have no proboscis. The *Ichthyobdellidae* are chiefly parasitic on fishes and, except a few fresh-water forms, are marine. Some of them, as *Branchellion*, are branchiate. The *Glossiphonidae* are richly represented in the fresh-water lakes and streams of North America by a great variety of species, most of which attach themselves to tortoises, whose blood they suck, or else they devour water-snails and small worms. A few are parasitic on fishes. In all of them the oral sucker is small and the eyes in one to four pairs placed near the median line. The *Herpobdellidae* contains slender, six or eight-eyed, pred-

aceous leeches, which are extremely abundant in fresh-water ponds and feed on small leeches and worms. They have no toothed jaws and the digestive tract is simple and straight. The *Hirudinidae* have 10 eyes, generally three-toothed jaws and a spacious sacculated digestive tract. Here belong the true blood-sucking leeches, the medicinal leech of Europe, and our native *Macrobdella decora*, also formerly largely employed in this country for blood-letting. The only terrestrial leech of the United States belongs to this family. It inhabits garden soil, feeds on earthworms, and is one of the largest leeches known. Consult: Leuckart and Brandes, 'Parasiten des Menschen'; Whitman, 'Quarterly Journal Microscopical Science' (1886); and Moore, 'Bulletin Illinois State Laboratory of Natural History' (1901).

Leeds, England, a municipal, parliamentary, and county borough and large manufacturing town, in the West Riding of Yorkshire, on the river Aire, 185½ miles north of London. The river, which in passing through the city is spanned by eight bridges, is navigable from its mouth in the Humber, and connects with the Leeds and Liverpool Canal. The town extends for about seven and one half miles from east to west, and about seven from north to south. From the extent of the manufactures the town is naturally smoky, and on the whole its appearance is not prepossessing, although much modern improvement has been effected. The most conspicuous building is the Roman-Corinthian town-hall, considered one of the finest municipal buildings in the kingdom. The greater portion of one wing is allotted to the Free Public Library, to which has been added the Fine Art Gallery. Leeds Infirmary, in the Gothic style, can accommodate 300 patients. Other notable buildings are the new general post-office, in the Renaissance style; the school-board offices, the Royal Exchange, the stock exchange, the Leeds Institute of Science, Art, and Literature; the Yorkshire College, the Grand Theatre, the new Empire Theatre, the grammar-school, the Coliseum (a public hall), etc. Among the places of worship are the parish church of St. Peter's; St. George's, with a tower and spire 160 feet high; Holy Trinity, a fine building in the Early English style; some of the Dissenting places of worship, and the Roman Catholic Church of St. Ann's. The chief educational institution is the Yorkshire College, a branch of the Victoria University (whose headquarters are in Manchester, having taken its origin in Owens College). It comprises two chief departments, a department of science, technology, and arts, including classics, modern languages, history, philosophy, mathematics, physics, chemistry, engineering, etc., and a well-equipped medical department. Other institutions are the Leeds Medical School (1894), Young Men's Christian Institution, a large training college for students for the Wesleyan ministry, and a literary and philosophical society. There is an admirable central library with several branches, the number of volumes being over 200,000. The charitable institutions of Leeds are numerous. Parks have been laid out by the corporation and recreation grounds, the chief being Roundhay Park (two miles from Leeds), 300 acres in extent and containing a lake of 33 acres. The fine ruins of

LEEK—LEEUWENHOECK

Kirkstall Abbey (3 miles from Leeds), with the adjacent grounds, presented to the town by Colonel North in 1889, form an attractive resort. The waterworks supply Leeds with water from the Washburn, a tributary of the Wharfe, the daily available supply being 28,000,000 gallons.

Leeds is and has been for generations the chief seat of the woolen manufacture of Yorkshire and has become the seat of other important industries. Chief of these is the wholesale clothing trade, in which several thousand hands are employed, many being also employed in the steel-works, iron-foundries, rolling-mills, tool and machine factories; in the boot and shoe factories and the leather trade, and in the cloth-cap trade, which is also becoming a great branch of industry. There are also locomotive works, tobacco manufactures, color-printing works, extensive chemical and glass works, important works for the making of drainage pipes, fire-bricks, ornamental terra-cotta and pottery ware, etc. One of the great sources of the wealth of Leeds is its abundant supplies of coal and iron. Nearly 100 collieries are worked in the district. The history of Leeds extends over more than 1,200 years, the town being mentioned under the name of Loid or Loidis by the Venerable Bede as the capital of a small British kingdom about 616. It was made a city in 1893, and its mayor was raised to the dignity of lord-mayor in 1897. The vicinity is crowded with villages, most of the inhabitants of which are employed in manufacturing for the Leeds market. Pop. (1901) 428,953.

Leek, a mild European kind of onion (*Allium porrum*), much cultivated for culinary purposes, being often partially blanched by heaping up the earth about the stem. It is used in soups and otherwise, and is the more tender and succulent the richer the soil. The stem is rather tall, and the flowers are disposed in large compact balls, supported on purple peduncles. The leek is a Welsh national emblem. It was well known to the ancient Egyptians, Greeks and Romans. Several species of the genus grow wild in the United States, furnishing the wild leeks, wild onion, field garlic, etc., of the country folks. The cows eat these plants gratefully in the spring, and their milk and butter is tainted in consequence. Compare GARLIC.

Lee's Mill, Engagement at. Lee's Mill is a point on the Warwick River, in Virginia, near which occurred the first considerable collision of the Peninsula campaign. The Confederate forces under Gen. Magruder occupied the line of the Warwick, and between Lee's Mill and Wynn's Mill Cobb's brigade threw up intrenchments and constructed redoubts for artillery. On 16 April 1862 Gen. W. F. Smith, with his division of Keyes' corps, was ordered by Gen. McClellan to reconnoitre Cobb's position, stop his work and, if deemed judicious, drive Cobb from it. Brooks' Vermont brigade was thrown forward, and after an artillery fire of more than six hours, part of the time from 18 guns, four companies of the 3d Vermont crossed the stream below a dam and seized the rifle-pits of the 15th North Carolina, but were driven back with severe loss. The effort was renewed later in the day, when, under cover of a heavy artillery fire, which was sharply replied to, detachments of the 4th, 5th, and 6th

Vermont endeavored to cross the Warwick, but were driven back. The Union loss during the day was 156 killed and wounded, and 9 missing. The Confederate loss did not exceed 75 killed and wounded. The result confirmed McClellan in his conviction that the line of the Warwick could not be carried by direct assault, and he directed all his efforts to the siege of Yorktown (q.v.). Consult: 'Official Records,' Vol. XI.; Webb, 'The Peninsula'; 'McClellan's Own Story'; Allan, 'History of the Army of Northern Virginia.'

E. A. CARMAN.

Lee's Surrender. See FARMVILLE

Leeser, Isaac, American rabbi and journalist: b. Neuenkirchen, Prussia, 12 Dec. 1806; d. Philadelphia 1 Feb. 1868. In his 18th year he removed to Richmond, Va., where he at first engaged in business. In 1829 he became Hazan or minister of Congregation Mikveh Israel of Philadelphia. His first work, 'The Jews and the Mosaic Law,' appeared in 1833, followed in 1837 by his sermons in two volumes. He edited in 1841 'Grace Aguilar's Spirit of Judaism,' and began in 1843 his monthly magazine, 'The Occident,' which he conducted until near the end of its 25th volume. In 1845 he published his Pentateuch in Hebrew and English, and in 1848 his edition of the 'Daily Prayers,' according to the German ritual. Retiring from the ministry in 1850, he issued an English translation of Schwarz's classic 'Geography of Palestine,' and an edition of the Hebrew Bible, with Jaquett. He began now an English translation of the Old Testament, completed in later years. In 1857 he was elected minister of the Beth El Emeth Synagogue, but continued his literary labors, editing 'Dias Letters' (1859); 'The Inquisition and Judaism' (1860); 'Mrs. Hester Rothschild's Meditations and Prayers' (1864); Grace Aguilar's 'Jewish Faith and Spirit of Judaism' (1864). In addition to his work as editor, translator, author and lecturer, he gave the impetus to nearly every Jewish charity in the city, while he suggested institutions that have since been established, so far-sighted was his vision. He was for decades the leader of the conservative party in American Israel and was aggressive and fearless in his opposition to the reform movement, whose progress, however, he could not check.

Leete, William, English colonial governor of Connecticut: b. England 1603; d. 1683. He was destined for the profession of law, and after being called to the bar practised in the Bishop's Court at Cambridge, but attaching himself to the Reformed faith, joined the Puritans who were emigrating in great numbers to America, and reached the western continent in 1637. He made his home in the New Haven Colony in 1639 and became a religious leader in Guilford, which he had helped to found. From 1658 to 1661 he was deputy governor of New Haven. From 1661 to 1662 he was governor, at which latter date the colony was united with Connecticut by royal charter. He was deputy governor of the Colony of Connecticut from 1669 to 1676, when he was appointed governor, a position he held till his death.

Leeuwenhoeck, 15'vén-hook, or Leuwenhoek, Antonius van, Dutch naturalist: b. Delft 24 Oct. 1632; d. there 26 Aug. 1723. In early life he was engaged in mercantile pursuits, but

LEEUWIN — LEFFERTS

applied himself during his spare moments to science, and attained the reputation of making the best microscopes in Europe. By his applications of the microscope, and researches in physiology, he attracted the attention of the Royal Society of London; and the greater part of his writings, containing accounts of his discoveries, were published in the English 'Philosophical Transactions.' He anticipated in his physiological discoveries much which has been confirmed in modern times. His assertions with regard to the circulation of the blood, the nature of the brain and nerves, and the structure of the crystalline lens, agree very nearly with the results of modern experiment. His investigation of the spermatic animalcules, which he claimed to have discovered in 1677, excited the curiosity of many naturalists, and they were afterward made the subject of much research and of many books by Buffon and others. Leeuwenhoek's life was passed in scientific research and in manufacturing optical instruments in his native city. His writings were collected and published in Dutch at Delft and Leyden. They also appeared in Latin (1695).

Leeuwin, lā'vīn or lē'wīn, **Cape**, the name of the point of land which is the southwestern extremity of Australia. It was named after the vessel Leeuwin, in which were the Dutch navigators who discovered in 1622 this part of the island. The light from the light-house can be seen 20 miles away. The place is subject to severe storms.

Leeward (lū'ard or lē'ward) **Islands**. See WEST INDIES.

Le Fanu, lē-fā'nū or lēf'a-nū, **Joseph Sheridan**, Irish journalist and novelist: b. Dublin 28 Aug. 1814; d. there 7 Feb. 1873. Having graduated from Trinity College, Dublin, he joined (1837) the staff of the Dublin University Magazine, at first as contributor, and afterward as editor and proprietor. Among modern Irish novelists he stands next in popularity to Charles Lever. 'The House by the Churchyard' appeared in 1863, and was succeeded by 'Uncle Silas' (1864), his most powerful work; 'Guy Deverell' (1865); 'The Tenants of Malory' (1867); 'The Wyvern Mystery' (1869); 'In a Glass Darkly' (1872); etc.

Lefebvre, **Jules**, zhül lē-fävr, French painter: b. Tournan, Seine-et-Marne, 10 March 1836. He was when a boy apprenticed to the trade of his father who was a baker, but his mother took pains to have him sent to Paris to study art, and he became the pupil of Léon Coignet. His 'Death of Priam,' exhibited in the Salon (1851) won for him the Grand Prix de Rome, since which he has gained many medals and honors. His 'Femme Couchée' in the Salon of 1868, a nude of singular freshness and power, established his reputation as an artist of the first rank, and the votes of the judges were divided equally between this picture and a painting of Corot's for the medal of honor, which was, however, bestowed on Brion. Among his best-known canvases are: 'Diana Surprised' (1879), purchased in the United States for \$7,000; 'Lady Godiva,' the Countess of Coventry, riding naked through the city—a painting also popularized by many reproductions; 'Psyche' (1883), now on exhibition as a loan in the Pennsylvania Academy of Fine Arts;

Psyche is represented with a star on her forehead, seated on a rock by the sea, and holding in her hands the fate of the world. 'La Vérite' in the Salon of 1870 attracted wide attention, and in recognition of its merits the painter was decorated with the cross of the Legion of Honor. 'Truth' is represented as holding aloft to the world a shining mirror. The action is impressive, the lines and proportion of the figure admirable, although the coloring is a little cold. As a painter of ideal heads Lefebvre has become widely popular. His 'Vittoria Colonna' is one of the most effective of these. But 'La Liseuse' (1889); 'La Poésie Antique,' 'Laure' and 'Violetta,' all exhibit the classic beauty, the repose and exquisite refinement of the ideal school. 'Clemence Isaure' is a study which is very human and life-like, the full lips and round chin suggesting physical life and passion while the bay leaves, with which the heavy locks of hair are wreathed, speak of poetic and intellectual power.

Lefebvre is one of the first of living French painters, and his influence is great in the Julien School where he is one of the instructors. Among the romanticists, classicists, realists and impressionists, he stands in the same class as Hector Leroux, Baudry, Bougereau, and Puvis de Chavannes, as an advanced idealist. Yet in opposition to such artists as Courbet, Manet and Bonnat, he is immensely popular, being in his love of ideal beauty and his refined technique, 'French of the French.'

Lefebvre, or **Le Fevre, Nicolas or Nicasius**, chemist, probably a native of France: b. about 1620; d. London 1669. He was educated at the Protestant Academy at Sedan, acquired a knowledge of chemistry and became his majesty's apothecary and distiller. Here Lefebvre found ample opportunity to pursue his favorite study. In 1660 appeared his 'Traité de la Chimie Théorique et Pratique,' which went through several editions, and was translated into German. In 1660 he was invited to London by Charles II. to take the post of royal professor and apothecary in ordinary to the household. He was also elected to the Royal Society, which had just been founded. In 1664 appeared a translation into English of his 'Traité,' entitled 'A Compleat Body of Chymistry.' His treatise on chemistry is compiled, according to his own account, from Van Helmont, Glauber, and Paracelsus, and is divided into the theory and practice of the art. The whole work is very well done, the author shows thorough familiarity with his subject, and his descriptions of apparatus, of substances, and of preparations are clear and systematic. His work served as a model for those of succeeding chemists, especially for that of Glaser, who replaced him in the Jardin des Plantes, and of Lemery.

Lefferts, Marshall, American engineer: b. Bedford, Long Island, 1821; d. 1876. After receiving a common school education he took up various occupations, finally settling down in the profession of electrical engineer, which he pursued from 1849 to 1860. During that time he was in the employ of the American Telegraph Company, and consulting engineer to the Atlantic Cable Company. He made many improvements in inventions in the department of electrical transmission while in the service of these companies. During the war he commanded the 7th

LEFFMANN — LEGEND

regiment. In 1867 he became connected with the news department of the Western Union Telegraph Company; two years later, president of the Gold and Stock Telegraph Company, and in 1871 he took control of the commercial news department, which had been purchased by that company.

Leffmann, Henry. American chemist: b. Philadelphia 9 Sept. 1847. He was graduated from Jefferson Medical College in 1869, and from the Pennsylvania College of Dental Surgery in 1884. He was elected assistant professor of chemistry at the Philadelphia Central High School and served from 1876 to 1880. He was port physician 1884-7, and 1891-2, and in 1888 was appointed but not confirmed, coiner United States Mint, political reasons interfering. Since 1888 he has been professor of chemistry at the Women's Medical College of Pennsylvania and professor of chemistry at the Wagner Free Institute of Science. Among his works are: 'First Steps in Chemical Principles'; 'Compend of Organic Chemistry'; 'Compend of Chemistry'; 'Analysis of Milk and Water Products'; 'Sanitary Relations of Coal Tar Products' (from the German); 'Structural Formulae for the Use of Students.' He has edited Reese's 'Medical Jurisprudence and Toxicology' (4th and 5th editions), and 'Allen's Commercial Organic Analysis' (Vols. I and II, 3d edition).

Legal Education. Instruction in law schools is given by lectures, by recitations from text-books, and by discussion and explanation of selected cases. Each of these systems has its advocates. In a majority of the schools instruction is given mainly by lectures. Next in popularity comes the method of recitations on lessons previously assigned. There are only a few schools that depend mainly on the discussion and explanation of selected cases. Dean Ashley of the New York University Law School writes as follows on this subject: "The leading universities repudiate the idea of any fixed method for teaching or studying law." Prof. Gray of Harvard says: "In all law schools, I suppose, the students learn from text-books, cases and oral instruction. At any rate they do so here. Each teacher is free to use these means as he pleases. The different professors do actually use them in different ways and proportions." Dean Keener of Columbia says: "There is no uniform method of instruction in this school. Each instructor is at liberty to pursue the method of instruction which in his opinion will be productive of the best results." See EDUCATION, PROFESSIONAL, IN AMERICA.

Legal Tender. See FINANCE.

Legal-tender Cases, in American finance, a series of cases before the United States Supreme Court, involving the question whether certain acts of Congress declaring United States notes a legal tender in payment of all debts, public and private, were constitutional. The cases were first argued in December 1867, and decided in November 1869, by a divided court. Five members of the court decided in the affirmative and three dissented. In 1871 after a re-organization of the Supreme Court, the cases were again brought up for argument. Again the court divided, five judges upholding the constitutionality of the act and four dissenting. All the judges agreed that Congress had full power

to direct issues of paper money. In 1878 Congress decreed that legal tender notes which had been redeemed or received in the Treasury from any source, should be re-issued and kept in circulation. This latter act was assailed in the courts and the Supreme Court decided, with but one dissenting voice, that Congress had full power to make United States notes a legal tender in the payment of private debts in times of peace as well as in times of war. This decision closed all judicial action upon the subject. Consult: Thayer, 'Legal Tender' in Harvard Law Review (1887); Legal Tender Cases (110 U. S. 421, 1884).

Le Gallienne, lē gal'li-ēn, Richard. English author: b. Liverpool, England, 20 Jan. 1866. He was educated at Liverpool College and after several years spent in business served as literary critic for the 'Star' and settled in London. Since 1902 he has lived in New York. Among his numerous published works are: 'My Ladies' Sonnets' (1887); 'Volumes in Folio' (1888); 'George Meredith' (1890); 'The Book-Bills of Narcissus' (1891); 'English Poems' (1892); 'The Religion of a Literary Man' (1893); 'Prose Fancies' (1894-6); 'Robert Louis Stevenson and Other Poems' (1895); 'Retrospective Reviews' (1896); 'The Quest of the Golden Girl' (1896); 'If I were God' (1897); 'The Romance of Zion Chapel,' a novel (1898); 'Travels in England' (1900); 'Odes from the Divan of Hafiz' (1903).

Legaré, lä-gré', Hugh Swinton. American statesman: b. Charleston, S. C., 2 Jan. 1789; d. Boston, Mass., 20 June 1843. He was graduated at the College of South Carolina in 1814, and subsequently studied at Edinburgh University. After a tour of Europe he returned home in 1820, and two years later entered upon the practice of law. In 1821 he represented his native city in the State legislature, and in 1830 was elected attorney-general. In the same year he established the 'Southern Review,' a quarterly, with Stephen Elliott. In 1832 he was appointed chargé d'affairs at Brussels. In 1836, he returned to the United States, and was at once elected to the lower house of Congress, but while there failed to please his constituents and was not re-elected. In 1840 he was appointed by President Tyler attorney-general of the United States. He was a brilliant orator and debater, and his contributions to the New York 'Review' on 'Demosthenes,' the 'Origin of Roman Law,' etc., were marked by much literary ability.

Legazpe, Miguel Lopez de, mē-gēl lō-pāth dā lä-gāth-pā. Spanish soldier: b. Zumarraga, Guipuzcoa, about 1510; d. Manila, Luzon, 20 Aug. 1572. He was for several years chief secretary of the government of the City of Mexico and in 1564 was made commander of the Spanish forces sent to the Philippine Islands. He sailed from La Navidad, Mexico, in November 1564, and reached the islands in the following February. He took possession of several of the islands and founded San Miguel in Cebu, in May 1565; began the subjugation of Luzon in 1570, and founded the city of Manila in May of the next year.

Legend, originally a term applied to collections of biographies of saints and martyrs, or of remarkable stories relating to them. In the

LEGENDRE—LEGGETT'S HILL

Middle Ages a collection of the lives of the saints was known by the name of *Legenda Sanctorum*, or *Historia Lombardica*. There is a celebrated collection, called the *Golden Legend* (*Aurea Legenda*), by Jacobus de Voragine, archbishop of Genoa, who died in the year 1298. It was translated into English by Caxton, and printed by him at the command of William, earl of Arundel, in 1483. Many of the mediæval legends were of an uncritical character, and along with true history often mingled much fable. In the course of time the legend came to mean only the fictitious parts of the story and became distinct from authentic history. It has now come to mean any unauthentic or improbable story handed down from ancient times. Legend is also used for the motto or words engraved in a circular manner round the head or other figure upon a medal or coin. The meaning of this term is similar to that of *inscription*; but the latter refers chiefly to the writing placed in the middle of the coin, while the legend surrounds it.

Legendre, Adrien Marie, à-drē-ōn mā-rē lē-zhōndr, French mathematician: b. Paris 18 Sept. 1752; d. Auteuil, France, 9 Jan. 1833. He was professor of mathematics in the military school at Paris and in 1783 became a member of the Academy. He was in 1787 employed by the French government with Cassini and Méchain, to measure a degree of latitude between Dunkirk and Boulogne, while English mathematicians did the same on the other side of the Channel, in order to determine the precise location of the observatories of Greenwich and Paris. In 1808 Legendre was appointed by the imperial government councillor for life to the university. He particularly distinguished himself by profound investigations as to the attraction of elliptical spheroids, and his method of calculating the course of the comets attracted great attention. His best known work is '*Éléments de Géométrie*' (1794; new edition, with additions and modifications by Blanchet 1845), which has been translated into English with notes by Sir David Brewster. He wrote also: '*Essai sur la Théorie des Nombres*' (1798); '*Nouvelle Méthode pour déterminer l'Orbite des Comètes*' (1805); '*Exercices du Calcul intégral, sur divers Ordres de Transcendantes et sur les Quadratures*' (1811-19); '*Traité des Fonctions elliptiques et des Intégrales eulériennes*' (1827-32); etc.

Léger, Paul Louis, pôl loo-ē lâ-zhâ, French scholar and author: b. Toulouse 13 Jan. 1843. In 1885 he was appointed professor of the Slav languages at the Collège de France, and has done much to awaken an interest in the history and philology of the Slav peoples by such works as: '*Slav Studies*' (1875); '*History of Austria-Hungary*' (1878), translated into English; '*Slav Tales*' (1882); '*The Save, Danube, and Balkan*' (1884); '*Bulgaria*' (1885); '*Russians and Slavs*' (1890); '*Russian Literature*' (1892).

Legerdemain, lēj-ér-de-mān', the art of performing tricks, or deceiving the human eye with apparent supernatural power. Legerdemain is usually carried on successfully by the aid of trick apparatus and machinery. Sorcery, enchantment, magic, necromancy, divination and perhaps astrology are in a sense all branches of legerdemain. For further details see MAGIC.

Leggett, lēg-êt, Mortimer Dormer, American soldier: b. Ithaca, N. Y., 19 April 1821; d. Cleveland, Ohio, 7 Jan. 1896. After graduating in medicine at Willoughby, Ohio, he studied law and was admitted to the bar in 1845. In the following year he was instrumental in organizing the first union free school system in Ohio. He was professor of pleadings and practices in Ohio Law College 1855-8, superintendent of the Zanesville (Ohio) public schools in 1858-62, and from 1862-5 served in the Federal army and was promoted to be major-general of volunteers in August 1865. From 1881 till his death he practised in Cleveland, Ohio.

Leggett, William, American journalist: b. New York 1802; d. New Rochelle, N. Y., 29 May 1839. He was educated at the college in Georgetown, D. C., and in 1822 entered the navy as midshipman, but resigned in 1826. He had in the previous year published a volume of poems, '*Leisure Hours at Sea, by a Midshipman of the U. S. Navy*', and in 1828 became editor of the '*Critic*', a weekly literary journal, soon united with the '*New York Mirror*', to which he contributed '*Tales by a Country Schoolmaster*' and '*Sketches at Sea*'. In 1829 he became one of the editors of the *New York Evening Post*, to which journal he was attached until 1836. He then commenced a weekly journal called the '*Plaindealer*', which attained a large circulation, but was soon discontinued through the failure of its publisher. In May 1839, he was appointed by President Van Buren diplomatic agent to Guatemala, but died suddenly while preparing for his departure. His '*Political Writings*', with memoir by Theodore Sedgwick, appeared in 1840. Leggett was remarkable among the journalists of his day as an unflinching advocate of freedom of opinion for his political opponents as well as for the men of his own party.

Leggett's, or Bald, Hill, Battle of, an engagement of the Civil War, near Atlanta, Ga. The battle of Peachtree Creek (q.v.), 20 July 1864, was a Confederate defeat. On the 21st Gen. Sherman advanced strong skirmish-lines to within about two miles of the works surrounding Atlanta. In the morning Leggett's division was ordered to carry a high, bare hill, situated about half a mile south of the Decatur railroad. Supported on the right by Giles A. Smith's division, Leggett advanced under cover of the hill itself, dashed forward when reaching its base, drove Cleburne's Confederates from it, and began to intrench. The Confederates made several vain efforts to retake it. From its summit Atlanta was in full view. Discovering at daybreak of the 22d that the advanced Confederate works had been abandoned, Sherman ordered a general advance along his line to occupy the city, and the movement began accordingly. During the night, however, the Confederate Gen. Hood had abandoned his advanced lines on the left and ordered Hardee's corps of four divisions to march entirely past Sherman's left and attack his left and rear. Giles A. Smith's division of Blair's Seventeenth corps held Sherman's left and Dodge's Sixteenth corps was some distance in rear of the centre of Blair's corps, and perpendicular to it. Blair fronted west, Dodge south.

LEGHORN—LEGISLATION

About midnight Hardee moved out of Atlanta by the McDonough road, and about day-break, when the troops had made a night march of 15 miles, and passed beyond Sherman's left, he halted, formed line, and gave his men needed rest. In half an hour the order was given to advance, and his corps went forward until Bates and Walther's divisions came to open ground, where they received a most deadly fire from Dodge's two Union divisions, which held them in check. Every effort to advance was repulsed with great loss, and Gen. Walther was killed. On the Federal side Gen. J. B. McPherson (q.v.), commanding the Army of the Tennessee, hastened troops to fill an interval between Dodge and Blair, rode to Dodge, and then toward Blair's line, and had gone but a short distance when he fell mortally wounded, being succeeded in command by Gen. John A. Logan. Meanwhile the left of Hardee's line had enveloped Giles A. Smith's division, attacking it in front, flank, and rear, Smith gradually yielding ground and refusing to connect his left with Dodge's right, the Confederates gradually advancing to the foot of Leggett's Hill. When Hardee's attack on Sherman's left and rear was being delivered, Hood ordered Cheatham's corps to attack in front, and the attack fell upon Leggett's Hill and the Fifteenth corps on the right of it, just as Leggett had repulsed an attack in his rear. Leggett, by desperate fighting, held his ground. The Confederates made repeated attacks until nightfall, when Hardee withdrew his right wing, leaving his left connected with the intrenched line in front of Atlanta. On the right of Logan's corps the Army of the Ohio was attacked by Smith's Georgia militia, which was readily repulsed. On Hardee's right Wheeler's cavalry attacked Sprague's brigade in Decatur, and for a time pressed it vigorously, but Reilly's brigade of the Army of the Ohio coming to its assistance, Wheeler was repulsed. The battle of Leggett's or Bald Hill was one of the greatest of Sherman's Atlanta campaign, and involved four corps of his army and two of Hood's. The loss of the Army of the Tennessee was 430 killed, 1,559 wounded, and 1,733 missing, with 10 guns; the entire Union loss during the day was about 4,000. The Confederate loss is not known; it has been variously estimated at from 6,000 to 10,000; it was probably between 5,000 and 6,000. Consult: 'Official Records,' Vol. XXXVIII.; Cox, 'Atlanta'; Sherman, 'Personal Memoirs,' Vol. II.; The Century Company's 'Battles and Leaders of the Civil War,' Vol. IV.

E. A. CARMAN.

Leghorn, lēg'hōrn or lēg'hōrn' (It. LIVORNO, lē-vōr'nō), Italy, a walled city and a seaport, in Tuscany, on the Mediterranean. It is the capital of the province of Leghorn. It is about 200 miles northwest of Rome and 60 miles west of Florence. It is a well built and clean city; the north part called Venezia Nuova, is intersected by canals along which are warehouses and stores. Leghorn has an inner and outer harbor and a good roadstead. Neither harbor will accommodate the largest vessels. In the outer harbor is a lighthouse, built in 1303. Some of the manufactures are straw hats (originally the famous Leghorn hats), leather, woolen caps, glass, paper, soap, coral ornaments, etc. Shipbuilding is one of its important industries.

The chief exports are olive oil, borax, wine, marble, quicksilver, candied fruit, hemp, hides, soap, raw silk, etc. The chief imports are sugar, cotton, coal, tobacco, grain, spirits, and petroleum. In the middle of the 16th century Leghorn had less than 800 inhabitants; but about this time it became a free port, the first one on the Mediterranean. After the decay of Porto Risano, a neighboring city, Leghorn grew into importance. Many of its ancient churches and dwellings are now in a good state of preservation, and are visited annually by many tourists. Some of the educational institutions are the Royal Commercial Marine Institute, the Royal Marine Academy, a library with over 60,000 volumes, a number of academies and seminaries. There are many charitable institutions for the sick and the poor, and for orphans. Leghorn is a popular summer resort, and its connection by electric lines with the bathing places and with beautiful villages in the vicinity make it a most desirable place of residence at any season of the year. Pop. (1901) 98,321.

Leghorn, a breed of domestic fowls. See **POULTRY**.

Leghorn Hats, hats made in Tuscany from straw-plait obtained from bearded wheat cut green and bleached. They are so called because imported from Leghorn.

Legion, in ancient Roman armies, a body of infantry consisting of different numbers of men at different periods, from 3,000 to above 6,000, often with a complement of cavalry. Each legion was divided into 10 cohorts, each cohort into three maniples, and each maniple into two centuries. Every legion had 60 centurions, and the same number of optiones or lieutenants and standard-bearers. The standard of the legion was an eagle.

Legion of Honor (*Légion d'Honneur*), a French order for the recognition of military and civil merit, instituted by Napoleon while consul 19 May 1802, and inaugurated 14 July 1804. The decoration originally consisted of a star containing the portrait of Napoleon surrounded by a wreath of oak and laurel, with the legend, 'Napoléon Empereur des Français'; on the reverse was the French eagle with a thunderbolt in his talons, and the legend, 'Honneur et Patrie.' The order has been remodeled several times. There are now five ranks or classes: ordinary chevaliers or knights, officers, commanders, grand-officers, grand-crosses. The profuse granting of the decoration of the order latterly brought the institution into discredit, and the number of chevaliers is now restricted to 25,000, the officers to 4,000, the commanders to 1,000, the grand-officers to 200, and the grand-crosses to 70. The star now bears a figure emblematic of the republic, with the inscription, 'République Française 1870,' on the reverse two flags, with the inscription, 'Honneur et Patrie.'

Legislation, or **Law-making**, a subject which naturally divides into four branches: the nature of its sanctions, or in other words the body from which it emanates; the methods of preparing and enacting it; classification by its subjects, as organic, general, special, or local; and by its objects, as substantive or constructive, and remedial or punitive.

i. The final sanction of any law must be the major part of the organizable force in a com-

LEGISLATURE

munity; since a law without force to compel obedience is mere counsel from an advisory body or the expression of an opinion, *brutum fulmen*. But the source which promulgates it need not be, as in modern states it usually is, an expressly constituted legislative body. The law may be an edict from a monarch; or a decree from an administrative council; or (as with State constitutions in general) the work of a popular convention, itself now usually called by a legislative body, but originally (see CONVENTION) the expression of the popular will through its leaders, not disowned by the people; or by judges who practically make new legislation by construing the old. A broad distinction between the United States and the continent of Europe in this respect is, that in the constitutional governments of the former, a large part of the work which loads the State and national legislatures here is done by administrative orders with the force of law. Each minister in the great departments of state promulgates executive decrees, of a sort which are classed as legislation and taken charge of by legislatures here (to the exhaustion of their time and energies needed for broader care over the public interests): city charters and county and town governmental regulations are there counted as administration, not legislation.

2. When entrusted to regular legislative bodies, the methods of imposing it on the community are practically divided into two, corresponding to Mr. Bagehot's classical division of governments into cabinet and presidential; or still more accurately, the difference as legislative bodies is between one supreme committee and an aristocracy of theoretically equal committees, of which some are grandees (see CONGRESS). In the former, the grand parliamentary committee called the cabinet initiates nearly all legislation, of its own motion or by adoption of outside proposals; shapes it under fire of discussion (in which the ministers take part), and dictates when it shall be voted on; and stands or falls with the general success of its measures. In the second or congressional method, also used in the State legislatures, each member introduces whatever bills he chooses; they are referred to committees, standing or special, who report and make recommendations on them (or not) at will, and those interested in their passage secure a vote when and if they can. The immense mass of projected legislation poured into legislatures under our system compels the most rigid rules as to all the stages of this process,—form, presentation, reference, readings, record, motions, balloting or ayes and noes, etc. In practically all our States the executive has a qualified veto on legislation (see EXECUTIVE). Much in favor now is the Referendum (q.v.), which throws the final responsibility on the people; but in no case have the results justified any confidence in it as an improvement.

3. Organic laws are those which form the working basis of an independent (or locally autonomous) community, assign rights and duties of sovereign and subject, distribute and delegate powers. These form the source of authority for all the working bodies which put into effect the organic provisions; to them, therefore, must be referred all questions as to the scope of their delegated powers, by legislatures and executive bodies. All that contravenes this organic law is "unconstitutional." From its

fundamental and far-reaching nature, it is always made difficult of change; and for the same reason, incessant and too often successful efforts are made, by over-zealous reformers, to foist into them all sorts of legislative measures so opposed to the wishes of a large section that speedy repeal is feared if not so intrenched. General legislation is that which affects the interest of the whole community, or if it practically affects special sections, does so by the chance of localized interests. The rules which should guide this are outside our province. Local legislation, that relating to particular municipalities or other State subdivisions, blends so indistinguishably with special legislation—that relating to specific individuals, companies, interests, etc.—that the evils are one, and the attempted restraints are of one sort. The latter (special) is of course far the most fertile source of direct pecuniary corruption, and much more abundant; but the "hold-ups" of municipal interests, or laws interfering with their government or finance, etc., have been and remain great sources of corruption also, for large money interests are often affected by them. So great have been the evils of this that many States have amended their constitutions to prohibit or restrain it; but in the case of municipalities, this is regularly, though with more than doubtful constitutionality, evaded by dividing a State into "classes," with but one in each class, and passing laws for the class. Special legislation for individuals or corporations can only cease with the abdication of legislative power over business; and the attempt to forbid it results in the worst class of it,—namely, the modification of general law to suit special interests.

4. Substantive or constructive legislation is that creating or defining rights and duties, or assigning powers; with this must always go, to make it a law, the provision of a penalty for disobedience, or at least a provision for enforcing obedience which implies the imposition of penalties already legal. The command or the permission to do something, in fact, implies a menace in case it is not done or the permission is interfered with. Destructive or amendatory law is the abolition of former laws; and a large part of the work of every legislature consists in undoing the work of its predecessors. But as this involves either passing others instead, or leaving in force still others, if nothing but the common law,—a mixture of legislature-made and judge-made legislation,—it belongs to the constructive order, paradoxical as it seems. Remedial legislation provides protection or remedies for wrong; this too needs its punitive accompaniment to be of any effect.

Legislature, in the United States, the law-making body of one of the States; in general, the law-making body of any constitutional state. The name always implies that there is not an autocracy promulgating self-validated decrees, but a body of representative citizens, who act for the entire citizenship in framing or consenting to their laws. It has been stated under LEGISLATION that laws need not emanate from an express legislative body; but in some shape all free modern states have such a body. The subject divides into four chief branches: (1) The origin and history of the body, and the general outcome; (2) the legal sources of its power and the methods of selecting it; (3) the

LEGISLATURE

extent and limits of its powers, its methods, and its periods; (4) the qualifications, tenure, and rights of its members. The first and second intertwine.

1. The original legislative bodies, like the Greek ecclesia and the Roman senate, were executive and administrative bodies also; public business was not yet differentiated. Under the empire, as the imperial power grew and the senatorial dwindled, legislation was confined to codes promulgated by the emperors, plus judge-made law. In the mediæval states, the king or prince was generally the fountain of legislation; but the Teutonic assembly, representing popular co-operation, survived in the favorable location of England, as the Witenagemot of the Saxon kingdoms. The Norman and Angevin kings replaced them with a council of leading nobles and clergy; but in the struggles with Henry III., Simon de Montfort called in the representatives of the towns. His system perished with him; but Edward I. revived it, for the sentiments of the chief sources of the royal supplies could not be disregarded. After asserting a check on one administrative department after another, the popular body wrested from the privileged orders first a share in and finally a monopoly of legislative action. The inviolability of its members, long claimed, was established against the Stuarts; the right to decide on the qualifications of its members was established against George III. by the Wilkes case. The separation of executive, judicial, and legislative functions, involved in this process,—since a representative body in a great state is unfit for the first two, though in the little Greek city-states they were combined,—had become a fixed principle of English public life by the 18th century, and was transferred to the English colonial governments. That nearly all had two chambers was due to the accident of the English parliament having that constitution; they were not due to the theory of "checks and balances," which on the contrary was evolved from the working of the parliamentary system. This system, nevertheless, commends itself by reason and experience, to prevent hasty or factious legislation, especially from great waves of popular feeling; and is used in nearly all legislative bodies. In part, this is because all other parliamentary systems, as the countries have emerged from absolutism or dependence and undertaken constitutional life, have been copied from those of England or the United States. This copying extends to all the general forms, and often mimics unessential details under entirely different circumstances from those which generate the originals. Thus, not only in the Congress but even more needlessly in the State legislatures, the lower house only (see *HOUSE OF REPRESENTATIVES*) can originate money bills; though both houses are equally popular bodies, and the English provision was part of a warfare between nobles and commons. The upper or less numerous house is also usually invested with the confirmation of treaties and appointments, and sometimes with some administrative functions; in the Congress the House prefers impeachments and the Senate tries them, and the States have copied this.

2. The old legislatures represented "estates" or orders of the state, the three great ones being nobles, clergy, and commons. The English parliament still does so, except that the first two are merged in one house and vote as one, in-

stead of separately as formerly. In essence this is the obvious and proper form of representation (by the great classes of interests and sympathies); but in a country where there are no classes, there is but one to represent, the whole people, and universal suffrage with popularly nominated candidates is the only workable method. Even where there are such, this method is general for the lower houses; but efforts are almost everywhere made to restrict the body of electors somewhat, and bar out the most ignorant, dangerous, or corruptible class. Property-holding or tax-paying are common, and educational requirements are much used, but not always for their avowed objects. The upper houses are sometimes chosen directly, as in the United States of Mexico and Brazil, but from larger districts than the lower, sometimes at large; sometimes indirectly, as in the United States and France; sometimes appointed, as in Germany, Switzerland, and Canada. In still others, it is neither elective nor appointive, but a mixture of hereditary and *ex officio*, or both, as in Great Britain and Austria-Hungary; sometimes a mixture of hereditary and elective, as in Prussia; sometimes of hereditary and appointive, as in Italy.

3. Legislatures may be divided according to their powers, into limited and omnipotent. The United States is the chief exemplar of the former; Great Britain and France represent the latter. Not only the State legislatures, but Congress, are limited to passing such laws as do not conflict with the Constitution, as interpreted by the Supreme Court; the States are still further bound by their State constitutions; and in both, President or governor can compel a reconsideration and a heavier majority. The enactments of most European parliaments are substantive law as soon as passed, with no superior authority; the English sovereign has a theoretical veto which he cannot use, the French president has none. In methods, all legislatures are hedged in by a great body of rules of their own making, found needful by experience; the choice and powers of the speaker, the appointment of committees, the method of introducing and acting on bills, the regulation of debate, the communication between the two branches and between either and the executive, the treatment of petitions, and many other matters, cannot be left to continual warfare. These rules are of great number and complexity, and throw the control of business entirely into the hands of experts (see *CONGRESS*): it has been said that a member of Congress needs an entire session to learn the rules sufficiently to take any effective part, and much of the time of all is spent in debating their application. A very important limitation is that on the freedom of debate by the American "previous question," French *clôture*, English "closure," in other governments "urgency of public business"—all are the same, and nearly all popular parliamentary bodies have been compelled to adopt it; the United States Senate being a conspicuous exception, and Great Britain a late and reluctant accession. Without it, the entire system of "government by discussion" may be made unworkable by a small knot of members playing tricks with the rules; with it free debate may be stifled, but the evil is the less of the two. Procedure must be open, save in "executive sessions" to make appointments. The matter of a quorum is settled by each for

itself, usually as a majority of the elected members; each also decides what shall constitute a majority vote, whether of members elected or members present. The former power of many legislatures to dissolve themselves has been everywhere restrained: in the States by limitation of term and of the frequency and length of sessions (usually now to biennial sessions, and often to 60 days, on a rather ludicrous theory); in Great Britain by limiting the length of a Parliament to seven years. The upper house in Congress and most States is made a continuing body, by so arranging the terms that only a part are elected on any one occasion.

4. The qualifications for the lower house are invariably citizenship; usually (though with growing exceptions) male sex; an age generally (though not always) higher than the voting age, usually 25, sometimes more; if a State of the Union, technical residence therein, and, by a custom with the force of law, residence in the district of election. Crime and pauperism are invariable disqualifications, and sometimes bankruptcy. The upper house in addition to these has almost invariably (except in the United States) a higher age limit, from 30 up to 40; often a property qualification; and when appointive, they are almost invariably from the upper business or professional ranks. The tenures are always much longer in the upper house than the lower: nowhere less than six years, nine in some, for life in many European states — save that in Germany and Switzerland they can be terminated at the will of the local governments that make the appointments. In the lower house it is from a minimum of one to a maximum of three, except in Great Britain, where it is for seven unless the Parliament is sooner dissolved. In all legislatures, the members are exempt from civil process while in actual session, even during journeys to and from home at recesses.

Légitime, François Denys, frān-swā dē-nē lä-zhē-tém, Haitian general: b. 1842. During the administration of President Salomon, he was accused of aspiring to the presidency, and accordingly went to Kingston, Jamaica, remaining three years, then returned to Haiti at the invitation of his followers, and on 7 Oct. 1888 was elected president of the provisional government. Gen. Thélémaque denounced the election as a job, and attempted to make himself president, but he was killed in the battle which ensued. Légitime was elected president of Haiti 17 Dec. 1888, but resigned in 1889, owing to the opposition of Gen. Hippolyte, and again retired to Jamaica. In 1896 President Sam granted a general amnesty, and he returned to Haiti.

Legouvé, Gabriel Ernest Wilfrid, gä-brē-ĕl ér-nă vél-frid lé-goo-vă, French dramatist and miscellaneous writer: b. Paris 15 Feb. 1807; d. 14 March 1903. In 1827 he won a prize of the Academy with a poem on the art of printing, 'Découverte de l'Imprimerie.' While instructor in the Collège de France 1847, he lectured on the history of woman's development; and later published: 'Moral History of Women' (7th ed. 1882), and 'Woman in France in the 19th Century' (1864). These works were received with great favor, and were followed by 'Science of the Family' (1867), and 'Messieurs the Young Folk' (1868). Meanwhile Legouvé was winning high distinction as a playwright with 'Louise de Lignerolles'; 'Adrienne Lecouvreur'

with Scribe (1840); 'Medea'; 'By Right & Conquest'; 'Miss Suzanne' (1867); 'Anne d'Kerwiler' (1870); 'Consideration'; etc. In 1882 he published: 'Recollections of Six Years,' and in 1890 'Winter Flower, Winter Fruits: Story of my Household.' In 1885 he became a member of the French Academy.

Legros, lē-grō', Alphonse, Anglo-French artist: b. Dijon, France, 8 May 1837. In 1851 he exhibited for the first time in the Salon, but finding small encouragement in France he removed to London in 1863, became a naturalized Englishman, and was appointed in 1876 professor at the Slade School in University College. His work, alike in painting, etching, and modeling, is strongly mannered, and as a colorist his range is somewhat limited. His more important pictures are the 'Anglers,' the 'Pilgrimage,' the 'Spanish Cloister,' the 'Benediction of the Sea,' the 'Baptism,' and the 'Coppersmith.' His etchings will prove in all probability his most enduring work, among the most noteworthy being his 'Death and the Woodman,' and 'Le Repas des Pauvres,' both marked by a fine breadth in conception and handling. His portraits are also of value.

Legu'min, or vegetable casein, a protein substance analogous to the casein of milk, obtained from beans, peas, lentils, vetches, and other leguminous seeds; the principle of the *Leguminose*.

Legumino'sæ, a natural order of herbs, shrubs, and trees widely distributed in all climates but most numerous in tropical and subtropical regions; growing upon all kinds of soil; exhibiting a great range of habit from creeping annual to climbing shrub; useful for a great variety of purposes — ornament, food, timber, fodder, and in the arts; and constituting the second largest family of plants, about 7,000 species distributed among about 450 genera. The species are characterized by alternate, stipulate, usually compound leaves; papilionaceous or sometimes regular flowers commonly arranged in racemes; monadelphous, diadelphous or occasionally distinct stamens, typically 10, surrounding a single simple pistil which generally becomes a pod or legume containing one to many seeds.

The species naturally fall into three sub-orders: (1) *Papilionaceæ*, with flowers resembling a butterfly; (2) *Casalpincæ*, with imperfectly or not at all papilionaceous corollas, which may sometimes be nearly regular; (3) *Mimosæ*, with small, regular flowers. The first group contains more than two thirds of the species. Its members are adapted for insect fertilization, especially by bees, which alight upon the lower petals, brush against the pistil which is thrust out by the insect's weight, then come in contact with the stamens and finally carry the pollen, which has been discharged, to other flowers. Thus the pistils receive pollen from stamens not in the same flower with them. In some instances they may also obtain pollen from these stamens, thus having a double chance to be fertilized. (See FLOWERS AND INSECTS.)

Perhaps the most interesting trait found in the order is the power possessed by the species of obtaining free nitrogen from the air by means of the tubercles or wart-like excrescences upon their roots. These tubercles are the homes of bacteria which have gained entrance to the

LEHIGH — LEHMANN

plant's tissue through the root-hairs; and are thus the result of irritation. The plants, it is believed, furnish the bacteria with carbohydrate food in return for the nitrogenous material prepared by them, thus exhibiting excellent examples of symbiosis (q.v.). Largely owing to this reciprocal action the legumes are valued as green manures, a fact long acted upon but unexplained until the last quarter of the 19th century, when Hellriegel and other investigators proved it, and even went further to show that soils poor in the bacteria could be inoculated profitably. See CLOVER; NITROGEN; ROOT-TUBERCLES; GREEN MANURING; VETCH; COWPEA; BEAN; LUPINE; ACACIA; LICORICE; INDIGO; SWEET PEA; MEDIC; LABURNUM; TAMARIND; MIMOSA.

Lehigh, lē'hi, a river of Pennsylvania which has its rise east of Wilkesbarre, in Luzerne County, and flows nearly south to a point about 12 miles below Mauch Chunk, where it breaks through the Blue Ridge. From here its course is southeast to Allentown, then northeast to Easton, where it enters the Delaware River, after a course of about 120 miles. In its upper course it is a rapid and picturesque mountain stream, broken by several falls. It passes through a rich coal and iron ore region, and serves as an outlet for the products of the mines. It was made navigable by a series of extensive improvements to Whitehaven, 84 miles from its mouth. The Lehigh Valley is famous for its beautiful scenery as well as for its valuable iron ore and anthracite coal deposits.

Lehigh University, an institution at South Bethlehem, Pa., founded by Asa Packer (q.v.), in 1865. He donated the land, 115 acres, upon which the buildings were erected, and \$500,000. At his death he bequeathed \$2,000,000, making in all a gift of about \$2,600,000. The object the founder had in establishing such a school was to give the young men of the Lehigh Valley an opportunity to acquire a complete education, technical, literary, and scientific, suitable to fit them for those trades and professions represented in the development of the peculiar resources of the rich mining territory in which it is located. The institution was incorporated in 1866 and its first class was graduated in 1869. It has six courses in the school of technology: civil engineering, mechanical engineering, metallurgy, mining, electrical engineering, and chemistry, leading to the degree of B.S. The school of general literature has a Latin-scientific course and a classical course, leading to the degree of B.A. Summer schools in the engineering courses are given each year. The master's degree in arts and science may be obtained by means of the graduate courses. The four years' course in metallurgical engineering leads to the degree of Metallurgical Engineer; and the four years' course in mining engineering leads to the degree of Engineer of Mines. Students have the advantage of frequently and regularly visiting the mines. The Bethlehem Steel Company and the Lehigh Valley Coal Company give the students many opportunities of study, especially when accompanied by an instructor. There are 14 college buildings: Packer Memorial Church, Packer Hall, laboratories, the Sayre astronomical observatory, a gymnasium, and other buildings which make a valuable group. The income is derived from the endowment fund

and tuitions. In 1903 the productive fund was \$1,250,000 and the income \$100,000. Some assistance has been received from the State. Connected with the school, in 1903, were 50 professors and instructors, and nearly 600 students. The library contains about 118,000 volumes. The graduates number (1903) about 1,200.

Lehighton, Pa., borough in Carbon County; on the Lehigh River, and on the Central of New Jersey and the Lehigh Valley R.R.'s; about 75 miles northeast of Harrisburg, the capital of the State, and 70 miles, in direct line, northwest of Philadelphia. It is a trade centre for a mining section of the county. Its chief manufactures are car-springs, flour, leather, stoves, furniture, brick, and mining tools. The borough owns the electric-light plant, but leases it to a private corporation who operates it. Pop. (1890) 2,959; (1900) 4,629.

Lehman, lā'man, Rudolf Chambers, English journalist, lawyer and authority upon rowing: b. near Sheffield, England, 3 Jan. 1856. He was educated at Cambridge and became a barrister of the Inner Temple in 1880. He has been a member of the staff of 'Punch' from 1890 and was editor of the London *Daily News* in 1901. He coached the Harvard crew in 1896 and 1897 and was given a dinner by the Harvard Club of New York on 10 April 1897. He has published among other works: 'In Cambridge Courts' (1891); 'Mr. Punch's Prize Novels' (1893); 'Isthmian Library: Rowing' (1897); 'Anni Fugaces,' verse (1901); 'Adventures of Picklock Holes' (1901).

Lehmann, lā'män, Lilli, German operatic singer: b. Würzburg 1848. Her mother, who was harp-player and prima donna under Spohr at Cassel, gave her the first musical instruction, and under her training Fräulein Lehmann developed a remarkable soprano voice. She made her début in Berlin (1870) and subsequently produced so good an impression that she was appointed imperial chamber singer in 1876. She became famous from the parts she took in the Nibelungen trilogy at Bayreuth, and sang in Wagner's operas in London (1884), and as principal soprano in the same operas at the Metropolitan Opera House, New York, her principal roles being Brünnhilde and Isolde.

Lehmann, Liza, English singer and composer: b. London. She is a daughter of Rudolf Lehmann (q.v.). She studied vocal music at London and Rome, and composition under Freudenberg and Hamish McKunn. On 23 Nov. 1885 she made her début in London; her success was assured, and she was received well throughout Great Britain and Germany. In 1894 she retired from public singing on her marriage with Mr. Herbert Bedford, a well-known composer. She devoted herself henceforth to composition and has produced works of freshness and originality, many of them tinged with a refined feeling which recalls the modern German romantic or emotional school. Her most successful works are the 'Persian Garden'; and 'The Daisy Chain' (1901).

Lehmann, Rudolf, Anglo-German painter and writer: b. near Hamburg 19 Aug. 1819. He was educated at the Johanneum, Hamburg, and proceeding to Paris studied painting under his brother Henry Lehmann; he was afterward the pupil of Cornelius and Kaulbach (q.v.) at

LEIB — LEIBNITZ

Munich. He went to Rome in 1839 and remained there 16 years. His largest picture is 'The Blessing of the Pontine Marshes by Sixtus V.' which was bought by the French government after being exhibited in France 1846. In 1866 he settled in London, and became a successful portrait painter. He has published: 'An Artist's Reminiscences' (1894); 'Men and Women of the Century' (1898).

Leib, lib, Michael, American politician: b. Philadelphia 1759; d. 1822. He was sent to the State legislature, and to Congress in 1798, where his pronounced political opinions made him conspicuous. Re-elected in 1800 and again in 1802, he opposed the administration of Jefferson, whom he had at first supported, and was politically associated with William Duane (q.v.) who published the 'Aurora.' Returned to Congress in 1804, he there vigorously opposed Gallatin and entering the Senate in 1808 was there especially hostile to both Madison and Gallatin. He left the Senate in 1814 to become postmaster of Philadelphia.

Leibnitz, Gottfried Wilhelm, göt'frēd vil'hēlm lib'nits, German metaphysician: b. Leipzig 21 June 1646; d. Hanover 14 Nov. 1716. From his earliest years he gave indications of remarkable genius and inherited from his father, who was a professor of moral philosophy, a love of historical study, and a taste for metaphysical speculation. In his sixth year his father died and he was removed from the Nicolai school at Leipzig and set free in his father's library. He soon ran through the ordinary German historical books and taught himself Latin by reading an illustrated edition of Livy. Before his 12th year he could translate Latin easily, and had begun Greek. In 1661 he entered the University of Leipzig. Here he became acquainted with the works of modern philosophers and mathematicians from Bacon to Descartes. In 1666 he was refused the degree of doctor of law on account of his youth, but immediately afterward received it from Altdorf, on which occasion his dissertation was so brilliant that a professorship was offered him, but he declined the position. The same year he visited Nuremberg, the centre of Rosicrucianism which he made the subject of profound study. At Nuremberg he met a former first minister to the elector of Mainz, and this led to his introduction to the elector himself, who subsequently employed the pen of the philosopher in furthering his own political plans. At that time Germany was threatened by France on the west and Turkey and Russia on the east, but even the sagacious arguments of Leibnitz failed to set a German prince on the throne of Poland (1669) or to induce Louis XIV. to send an expedition to Egypt, ostensibly for the purpose of crippling the commerce of Holland, but really in order that the armies of France might be diverted from attacking Germany. It was the discovery by Napoleon of Leibnitz's letter on this subject (1803) that led to the First Consul's futile campaign in the Nile Valley. But the negotiations on this subject had an important result in sending Leibnitz to Paris, where he made the acquaintance of Arnauld, the Port Royalist, Huygens, the Christian physicist, and Malebranche, the mystic psychologist. From Paris he went to London (1673) where he was elected fellow of the Royal Society. His studies

in mathematics meanwhile resulted in the discovery of differential calculus. The discovery was claimed also by Newton, but it would appear, as in the case of Wallace and Darwin, that two great minds working independently on parallel lines had simultaneously arrived at the same conclusions. In 1676 Leibnitz was invited by the Duke John Frederick of Brunswick-Lüneburg to take charge of his library in the palace at Hanover and to employ himself in writing the history of the Brunswick-Lüneburg family. While thus engaged he found time to compose his 'Systema theologicum' (1686) in which he attempted to discover a common ground in the details of belief for the Roman and Reformed Churches. He also corresponded with Bossuet on this subject. He removed to Berlin in 1700, and founded the academy of which he became president for life. At that date began his intimacy with the electress Sophie Charlotte of Brandenburg, and her mother, Princess Sophie of Hanover. For five years Leibnitz enjoyed the friendship and intellectual society of the former, and her death in 1705 was a blow from which he never recovered. In 1712 at Vienna Leibnitz, who was strangely covetous of honors, was made imperial privy councillor and baron of the empire.

During the last 30 years of his life he was a laborious writer. Not only was his history of Brunswick completed, though fated to be unpublished until 1843, but he left scarcely any subject untouched by his tireless pen. Theology, jurisprudence, mathematics, metaphysics, history, politics, economic science and philology became in turn subjects of his comment. While his greatest claim as a thinker is based upon his philosophic system he has never stated his views in a single coherent treatise. In 1696 he made a clear utterance on some important points in replying to Locke's 'Essay on the Human Understanding.' In 1710 appeared what we may call an exposition of his philosophy from the deistic standpoint, 'Essais de Théodicée sur la Bonté de Dieu, la Liberté de l'Homme, et l'Origine du Mal.' In 1704 he stated his theory of physics in his 'Monadologie,' a modification of Democritean atomism. He spent his last days in utter neglect, tortured by disease, forgotten by his friends and still grieving for the loss of the only woman he had ever loved. He was buried without any religious office and with only a single mourner to watch the grave close over one of the greatest men in the intellectual world of modern times.

Leibnitz in private life was almost secluded from the world. He was somewhat unfitted for social intercourse by his irritability and dislike of contradiction, though in the discussion of large questions or problems he was tolerant of other men's views and eager in acquiring information from any person. While almost ascetic in his control of appetite, he has been charged with avarice, and it would sometimes seem as if his thirst for temporal honors and public recognition was beneath the dignity of his truly gigantic mind. In philosophy Leibnitz may be classed with the Cartesians. If, as Coleridge says, 'Every man is either an Aristotelian or a Platonist,' Leibnitz was a Platonist. He comes in conflict with Locke on the subject of knowledge and denies that the mind is *tabula rasa*, but perhaps his views may best be summarized

LEIDY—LEIGHTON

under the three familiar terms of his philosophic system. The first is what he calls the principle of Sufficient Reason. The meaning of this phrase seems to be, that there are two kinds of human cognition, that of intuition, which applies to truths that are self evident, such as the fact of identity, as, John is John, and that which relates to the content of John and asserts something more than his self evident identity. The content of John consists of facts to be proved, such as his character, his intellectual power, his natural disposition. Unless the statements concerning these things can be proved true they are not true. Leibnitz here makes a distinction between the analytical and synthetical sciences, and maintains that by the application of the Sufficient Reason, the higher sciences which are synthetical can be placed on as solid a basis of truth as those which are merely analytical, and based on the recognition of identity. It is in this way that he would build up speculative knowledge whether physical or metaphysical. Leibnitz revived the profoundest discovery of Greek philosophic subtlety, when he propounded his atomism or "monadology" as he calls it. But the atoms of Democritus were merely material, those of Leibnitz are spiritual-self-determined beings, the highest of which is God. These atoms, he says, have neither parts, extension nor figure. They are but force centres, for substance can only be conceived of in its ultimate analysis as force. Space, matter and motion are merely phenomena. The greater amount of activity or power of perception the higher and more perfect is the monad. No two monads are alike, they vary by the clearness and intensity of the reflection which they receive of the universe. Yet they are all in harmony and so constituted as to form one universe with God as its efficient cause and the establisher of this harmony, which results in the existence of the best possible world. We have seen that Leibnitz is a spiritualist, and while he would make the monads of the body and the monads of the soul of different orders, he explains their communication with each other by the rule of what he calls Pre-existent Harmony. How do the emotions or volition of the soul operate upon the body? Here he finds a solution in "pre-established harmony," as question-begging a term as the *κίνησις κατά ταρεύκλων* of Epicurus, the occasionalism of Malebranche, or the dualism of Spinoza. "God," he says, "created the soul in such a manner at first, that it should represent within itself all the simultaneous changes in the body; and that he has made the body also in such a manner as that it must of itself do what the soul wills; so that the laws which make the thoughts of the soul follow each other in regular succession, must produce images which shall be coincident with the impressions made by external objects upon our organs of sense; while the laws by which the motions of the body follow each other are likewise so coincident with the thoughts of the soul as to give to our volitions and actions the very same appearance as if the latter were really the natural and the necessary consequences of the former." This is the famous theory of Pre-established Harmony.

Consult: Erdmann, 'Leibnitii Opera Philosophica' (1839); Fischer, 'Leibnitz und seine

Schule'; Duncan, 'English Translation of Leibnitz's Works' (1890); Dewey, 'New Essays of Leibnitz' (1888).

EPIPHANIUS WILSON, M. A.,
Editorial Staff of the 'Encyclopedias Americana.'

Leidy, lī'dī, Joseph, American naturalist: b. Philadelphia 9 Sept. 1823; d. there 30 April 1891. He was graduated M.D. at the University of Pennsylvania in 1844, and in 1853 was elected to the chair of anatomy in that institution, a post which he long filled, as well as that of professor of natural history in Swarthmore College, Pa., to which he was appointed in 1871. He was the author of many valuable memoirs, chiefly published in the 'Proceedings of the Academy of Natural Sciences,' the 'Transactions of the American Philosophical Society,' and the 'Smithsonian Contributions to Knowledge.' Among them may be cited: 'Ancient Fauna of Nebraska' (1853); 'Cretaceous Reptiles of the United States' (1865); 'Fresh Water Rhizopods of North America' (1879).

Leif Ericson. See ERICSON, LEIF.

Leighton, lä'tōn, Frederick, Lord, English painter: b. Scarborough 3 Dec. 1830; d. London 25 Jan. 1896. He received some lessons in art at Paris as early as 1839, and then followed further instruction at Rome. At 14 he entered the Royal Academy of Berlin and subsequent art studies were made by him at Frankfort, Brussels and Paris (1850). From Rome he sent to the Royal Academy exhibition of 1855 his picture of 'Cimabue's Madonna Carried Through Florence'—a work which called forth general admiration, and was purchased by the Queen. He resided mostly in Paris for the next four years, studying and painting, and to this period belong, among other works, 'The Triumph of Music' (based on the story of Orpheus and Eurydice); 'The Fisherman and the Siren,' and 'Romeo and Juliet.' Having finally settled in London, he was elected in 1864 an associate of the Royal Academy, and in 1869 a full academician. In 1878 he succeeded Sir Francis Grant as president of the Royal Academy, was knighted, and was also named an officer of the Legion of Honor. In 1886 he was created a baronet, and on 1 Jan. 1896 was raised to the peerage. From among his numerous works may be singled for special mention: 'Paolo and Francesca' (1861); 'Jezebel and Ahab' (1863); 'Orpheus and Eurydice' (1864); 'Hercules Wrestling with Death' (1871); 'Elijah in the Wilderness' (1879); 'Hero Watching for Leander' (1887); 'Captive Andromache' (1888); 'Greek Girls Playing at Ball' (1889); 'The Bath of Psyche' (1890); 'Lachrymæ,' now in the Metropolitan Museum, New York; as also the two large frescoes at the South Kensington Museum, representing respectively the 'Arts of War' and the 'Arts of Peace.' He achieved a high place as a sculptor by his 'Athlete Strangling a Python' (1876), and his 'Sluggard' (1886). The special merit of his work lies in the perfection of his draftsmanship and design; his coloring, though possessing the unfailing charm of harmonious arrangement, is only thoroughly satisfactory from the decorative point of view. A fine poetic quality conjoined with elegance in drawing and great refinement in execution, mark his whole work. His 'Addresses to the Students of the

LEIGHTON—LEIPSIC

Royal Academy' appeared in 1896. Consult 'Lives' by Mrs. Lang (1885); Rhys (1895).

Leighton, Marie Connor, English novelist: b. Clifton, near Bristol. She was married to Robert Leighton (q.v.) with whom she has written several novels mentioned under his name, and is the author of 'The Harvest of Sin'; 'A Napoleon of the Press' (1900); 'Vengeance is Mine' (1902); 'Was She Worth It?' (1902); etc.

Leighton, Robert, English journalist and novelist: b. Ayr, Scotland, 5 June 1859. He was the son of Robert Leighton, a Scottish poet, was educated at Liverpool, was editor of the Bristol 'Observer' 1886-7, and has for many years been connected with the various periodicals published by Harmsworth. He married Marie Connor in 1889 and with her wrote 'Convict 99'; 'Michael Dred, Detective'; 'In the Shadow of Guilt' and other fictions. He has written by himself 'The Pilots of Pomona' (1892); 'The Thirsty Sword' (1893); 'The Wreck of the Golden Fleece' (1894); 'Olaf the Glorious' (1895); 'The Golden Galleon' (1897); etc.

Leipsic, lip'sik, or **Leipzig**, lip'tsīg, Germany, the largest town of Saxony, and the fourth largest in the German empire, situated in a broad, fertile plain at the confluence of the rivers Elster, Pleisse, and Parthe. The city comprises the inner town, the inner and outer suburbs (Vorstädte), the more outlying suburbs (Vororte), incorporated with the city in 1889-92, all traversed and connected by electric street railroads. The former fortifications surrounding the inner city have been replaced by fine streets and promenades. The old city still retains much of its ancient appearance, but the modern suburbs are characterized by broad streets and imposing buildings. Among the squares of the city are the Marktplatz, with a Siegesdenkmal; the Augustusplatz, one of the largest in Germany, with a splendid fountain; the Königplatz, the Johanniskirche, with a Reformation monument (Luther and Melanchthon); and the Rossplatz; and among the other monuments worthy of mention are those of Gellert and Fechner in the Rosenthal, an extensive park in the northwest, between the Elster and the Pleisse; of Hahnemann, Leibnitz, Grassi, Mendelssohn, and Bismarck; together with the more recent memorial of the Volksschlacht. Besides the parks and open spaces just mentioned, Leipsic includes, among many others, the Johannapark, the Grassipark; the König Albert Park, the scene of the 1897 exhibition; the Johannisthal, with an observatory; the botanical garden; the zoological garden, recently much extended; the palm garden, opened in 1899. The most noteworthy churches of the city are the Thomaskirche (13th century), rebuilt 1885-9; the Nikolaikirche (11th century), recently restored; the University or Paulinerkirche (1240), restored 1896-9; the Matthäikirche, restored 1879; the Johanniskirche (14th century), rebuilt and re-consecrated in 1897, and containing the remains of Sebastian Bach and Gellert; the Peterskirche; the Lutherkirche; the Andreaskirche; two modern Roman Catholic churches; an Anglo-American church; a synagogue; and churches of other denominations. Of non-ecclesiastical buildings the most notable are those of the university, which was

founded in 1409, and now has 220 professors and lecturers, and over 3,200 students. These buildings are mostly modern, especially the Albertinum, erected in 1890-6 in accordance with the plans of A. Rossbach for completing and renewing the whole group. The university library (the Albertina) contains 440,000 volumes and over 4,000 manuscripts. Other buildings and institutions are: the old Rathaus (16th century); the new Rathaus, in course of construction on the site of the Schloss Pleissenburg, a 13th century building, once the citadel of the town, and famous as the scene of Luther's disputation with Eck in 1519; the old exchange (1678), now the meeting-place of the town council; the new exchange in Renaissance style; the Königshaus (17th century), the residence till 1829 of the Saxon princes; the old Gewandhaus, where the celebrated Gewandhaus concerts were long held; the new concert-hall; the imperial bank building, in German Renaissance style; the municipal library (1899), containing 110,000 volumes and many manuscripts; the municipal museum, in Italian Renaissance style; the chief post-office; the new book exchange, the headquarters of the German book trade; the Buchgewerbehaus (1897), with a Gutenberg hall; the panorama building; the Grassi Museum (1896), now including the collections of the former museums of industrial art and ethnology; the police office; the building of the Land and Amtsgericht, enlarged in 1895-6; the building of the Imperial Court, completed in 1895; the new conservatory of music; the old and the new theatre; the Krystallpalast, including concert halls, etc.; the market hall; the large Johannis hospital; a deaf and dumb and a blind institution; the hospital of St. Jakob; the Triesches Institut, for women; three gymnasia, namely, the Thomas-schule (1221), the Nikolaischule (1511), and the royal Gymnasium, a Real Gymnasium; several Realschulen and many other schools; a Handelshochschule, or High Commercial School (1898), the first in Germany; a school of industrial art; a Royal Academy of Arts; and the new infantry barracks at Möckern. Leipsic has railway communication with all the chief towns of Germany, and its situation makes it of great importance as a trading centre. It has three large annual fairs, which have been held ever since the 12th century. It is the headquarters of the book trade in Germany, and takes a foremost place among European towns in the many industries associated with the publication and printing of books. Its other industries include iron-founding, cotton-spinning, wool-combing, the weaving of jute and linen, brewing, sugar-refining, distilling, and the manufacture of machinery, electrical plant, agricultural implements, ethereal oils, dyes, essences, soaps, perfumes, wax-cloth, chocolate, tobacco, paper, leather, tapestry, cement, musical and other instruments, etc. Leipsic is also a world market for furs and all similar goods. The name Leipsic, from the Slavonic *līpa*, a lime-tree, is found applied to a Slavonic fishing village near the present site of Leipsic about 1017. The history of the town during many centuries is one of gradually extending importance. It suffered much during the Thirty Years' war at the hands of both combatants. Its position of pre-eminence in the book trade dates from the latter half of the 17th century. During the earlier years of the 18th century the town became the

LEISLER — LEITMOTIV.

centre of a literary movement under Gottsched. Leipsic and its neighborhood suffered greatly during the Napoleonic wars, and on 16-19 Oct. 1813 a series of severe battles fought around the town resulted in a crushing defeat of Napoleon, and the retreat of the French from Germany. During the war of 1866 Leipsic was occupied by Prussian troops for 18 months. In 1879 the Supreme Court of Justice for the empire was established in the city. Pop. (1900) 455,089.

Leisler, lis'ler, Jacob, American colonial political leader: b. Frankfort-on-the-Main, Germany; d. New York 16 May 1691. He came to America as a private soldier in the service of the Dutch West India Company, and was for a time engaged in trade at Albany, and later settling in New York was appointed in 1783 one of the "commissioners" (judges) of the court of the admiralty. In 1689 he was the leader of the insurrection against Governor Nicholson, supported mostly by the militia and the lower classes; the fort and the public funds were seized on the 31st of May, and Leisler a few days later declared for William and Mary, asserting his acts to be necessary for the "preservation of the Protestant religion." A committee of safety was formed, who on 8 June commissioned Leisler as "captain of the fort." In this capacity he at once began to repair the fort, and strengthened it with a "battery" of six guns beyond its walls, which was the origin of the public park still known as the Battery. Nicholson and the council of the province, with the authorities of the city, attempted by pacific means to prevent the uprising, but without effect. Becoming finally alarmed for their own safety, the lieutenant-governor sailed for England, and the mayor with the other officials retired to Albany. On 16 August the committee of safety appointed Leisler "commander-in-chief of the province," with the full power of a governor in all matters civil and military. He next attempted to reduce Albany and the northern parts of the colony, which from the first had refused to recognize his authority, but was for some time unsuccessful; Albany finally submitted to him after the Indian attack on Schenectady (1690). In December arrived a despatch from William and Mary directed "to Francis Nicholson, Esq., or in his absence to such as for the time being takes care for preserving the peace and administering the laws in his majesty's province of New York." This Leisler construed as an appointment of himself as the king's lieutenant-governor. He therefore dissolved the committee of safety, swore in a council, and assumed the style of a royal lieutenant-governor and commander-in-chief. After the massacre at Schenectady he engaged with great vigor in the expeditions against the French, and equipped and despatched against Quebec the first fleet of men-of-war ever sent from the port of New York. A few months later Major Ingoldsby arrived with the news of Sloughter's appointment as governor, and demanded possession of the fort, which Leisler refused. On Sloughter's own demand immediately upon his arrival in March 1691, he likewise refused to surrender it, until convinced of Sloughter's identity, and the latter had sworn in his council. Leisler was immediately imprisoned, charged with treason and murder, and shortly after tried and condemned

to death. His son-in-law and secretary Milborne was also condemned on the same charges. These trials were manifestly unjust; the judges were the personal and political enemies of the prisoners, and Sloughter for some time hesitated to sign the death warrants. Leisler's son secured from the English Parliament the reversal of the bill of attainder in 1695; and the confiscated estates were also returned to the heirs. Consult: Brodhead, 'History of New York'; 'Documentary History of New York', and E. S. Brooks, 'In Leisler's Times' (a historical story).

Leith-Adams, Mrs. See LAFFAN, BERTHA JANE.

Leith, lēth, Scotland, a seaport and parliamentary burgh in the county of Midlothian, and a northeastern suburb of Edinburgh, on the south shore of the Firth of Forth, on both sides of the Water of Leith. It is connected with Edinburgh by Leith Walk and other lines of streets, and by branch lines of the railways centering in Edinburgh. Among the principal public buildings are the custom-house, exchange buildings, court-house, Trinity House, corn-exchange, the new and well equipped Leith Academy, including the Leith Technical College, and there are fine parks and public golf links. The chief manufactures are ropes, sail-cloth, oil-cake, paints, colors, artificial manures, and there are shipbuilding-yards, iron-foundries, engineering works, flour-mills, oil-mills and refineries, steam saw-mills, large maltings, an ice factory, etc. The foreign trade is chiefly with the Baltic and the principal French and German ports, and there is a trade in grain, flour, etc., with the United States and Canada. There are extensive wet-docks, and several public graving-docks, capable of receiving the largest vessels. Leith is a very ancient town, its earliest charter dating from 1128. Pop. (1901) 77,439.

Leitha, li'tā, Austria-Hungary, a river rising in Lower Austria, and flowing northeast for the greater part of its course of 90 miles along the frontier of Austria and Hungary, until it joins the Danube at Altenburg. The Leitha Mountains rise between it and Lake Neusiedl, and it has a factitious importance in its application to Hungary as Trans-leithan and Austria as Cis-leithan.

Leitmotiv, lit'mō-tēf, in music, the leading theme, the characteristic phrase, which occurs over and over again in the same composition, in reference to the same person, phrase of feeling or scenic complication of intense passion or action. The phrase strikes the note of these several crises or conjunctures and recurs whenever they are repeated. While many operatic composers, such as Mozart and Weber, have employed the expedient of the leading theme, Wagner does so more than any other modern musician. In his *Leitfäden*, or analyses of his operas, in which he lays bare some of the secrets of his artistic workmanship, he shows that he has consciously individualized every one of his characters, every change in the scenery or action of the drama, or in the emotions and moods of the *dramatis personæ*, by the introduction of a specific musical theme, which he employs throughout the opera to suggest the same thing. This theme is worked upon and varied with the masterly skill which Wagner possesses in fugue and part writing. Thus in

LEIXNER-GRÜNBERG—LELAND STANFORD JR. UNIVERSITY

his 'Parsifal,' Klingsor, Kundry, Parsifal, Amfortas, and the Flower maidens are all ushered in with a special leading theme for each. There is a special theme for the Eucharist, for the spear (*Speermotiv*), for the Holy Grail (*Gralmotiv*). The children's voices raise a strain 'Faith is still alive' to the notes of the *Glaubensthema*, or faith-motive. There is a *Leidensmotiv*, to express the grief of Amfortas; there is the Doormotiv, expressing the promise of help; the Zaubermotiv, suggesting the devilish power of witchcraft, while the mother's sorrow is suggested by the Motiv des Herzleids, the heart-grief's theme. The Bell-theme, with its pealing sound, the Ride-theme, suggesting the clatter of horsehoofs, the Good Friday theme, with its characteristic chords, each in its way, are powerfully suggestive, and when once recognized, their recurrence has a powerful effect.

Leixner-Grünberg, līks'nér grün'bērg, Otto von, German poet and critic: b. Saar in Moravia 24 April 1847. Among his poetical works are: a volume of 'Poems' (1868); the drama 'Resurrection of Germany' (1870); 'Twilight' (1886); 'Proverbs and Satiric Rhymes.' He has also written short stories: 'The Two Marys'; 'Memento Vivere'; 'Princess Sunshine' (1882). Still other works are: 'Marginal Notes by a Hermit'; 'Gossamer' (1886); 'Gossip Letters to a Young Matron' (1890); 'Lay Sermons' (1894). His 'History of German Literature' (1879-82) is a notable work.

Le'land, Charles Godfrey, American author: b. Philadelphia 15 Aug. 1824; d. Florence, Italy, 20 March 1903. He showed poetic talent in youthful contributions to newspapers, and a growing genius, marked by unusual versatility, during his college days at Princeton, where he was graduated in 1846. He studied afterward at Heidelberg, Munich, and Paris, giving special attention to modern languages, philosophy, and æsthetics. In 1848 he took part in the revolutionary uprising in Paris; the same year returned to Philadelphia and studied law; was admitted to the bar in 1851, but gave up the legal profession and devoted himself to literary pursuits, becoming prominent in various fields of journalism and authorship. For a time he was editor of the New York 'Illustrated News'; in 1861 established the 'Continental Magazine' in Boston, and two years later returned to Philadelphia, where for several years he edited the *Press*. During the Civil War he published 'The Book of Copperheads,' a political satire. From 1869 to 1880 he resided chiefly in London. In England and on the Continent he studied gypsies and gypsy lore, in which he became one of the leading authorities of his time. His career as poet, ethnologist, and traveler, with its mingling of literary avocations, was invested with an element of romance, and his more serious work was lightened by the interchange of humor. At the same time his achievements show the practical talents of a man of business. When in 1880 he once more returned to Philadelphia he was instrumental in establishing industrial teaching in the public schools, in furtherance of which he wrote a number of manuals and gave his supervision to the work. From 1886 he lived in Europe, mainly in Florence. He wrote and translated a large number of works, remarkable for variety

as well as for literary value, the best known and most popular of which are 'Hans Breitmann's Ballads' (1867-70, 1895), written in 'Pennsylvania Dutch,' his translations from Heine, including 'Pictures of Travel' (1856), and 'Heine's Book of Songs' (1862), 'English Gypsies and Their Language' (1873), 'English Gypsy Songs' (in collaboration, 1875), 'The Gypsies' (1882), and 'Gypsy Sorcery and Fortune-Telling' (1892). Among his other writings are: 'The Poetry and Mystery of Dreams' (1855); 'Meister Karl's Sketch-Book' (1855); 'Sunshine in Thought' (1862); 'Legends of Birds' (1864); 'The Music-Lesson of Confucius' (1870); 'The Egyptian Sketch-Book' (1873); 'Fu-Sang; or the Discovery of America by Chinese Buddhist Priests in the Fifth Century' (1875); 'Johnnykin and the Goblins' (1876); 'Pidgin-English Singsong' (1876); 'Abraham Lincoln' (1879); 'The Minor Arts' (1880); 'Algonquin Legends of New England' (1884); 'Etruscan-Roman Remains in Popular Tradition' (1892); 'Autobiographical Memoirs' (1893); 'Songs of the Sea and Lays of the Land' (1895); 'Mending and Repairing' (1896); 'One Hundred Profitable Acts' (1897); 'The Unpublished Legends of Virgil' (1899); and (his last work) 'Kuloskap the Master, and Other Algonkin Poems' (1903), a volume of Indian folklore in verse, written in collaboration with John Dinley Prince.

Leland, lēl'and, or **Leyland**, John, English antiquary: b. London about 1506; d. there 18 April 1552. He was educated at Cambridge, Oxford, and Paris. Returning home he took holy orders, and Henry VIII. made him his chaplain and librarian. In 1530 he became rector of Pepeling, near Calais; in 1542 he received the rectory of Haseley, Oxfordshire, and he was a prebend of Salisbury Cathedral. In 1533 he received the title of royal antiquary, and was empowered, by a commission under the great seal, to search for objects of antiquity in the archives and libraries of all cathedrals, abbeys, priories, etc., in consequence of which he spent six years in traveling and collecting materials for the illustration of the history and archaeology of England and Wales, but died without having completed his undertaking. The great bulk of his collections was placed in the Bodleian Library. The first part to be published was the 'Commentarii de Scriptoribus Britannicis,' issued in 1709 by Anthony Hall. In 1710 Hearne published the 'Itinerary' in 9 vols., and five years later the 'Collectanea' was issued by him in 6 vols. Leland wrote Latin poetry with considerable elegance, and a collection of his miscellaneous Latin verse and epigrams was published in 1589.

Leland Stanford Junior University, a co-educational institution at Palo Alto, California, about 35 miles southeast of San Francisco, in the Santa Clara Valley. The University Campus comprises 9,000 acres of land, partly in the level of the valley and partly rising into the foothills of the Santa Moreno Mountains which separate it from the Pacific Ocean, 33 miles beyond. The Bay of San Francisco lies in front at a distance of three miles and across it are the mountains of the Diabolo range.

The University was founded by Leland Stanford (q.v.) and his wife, Jane Lathrop Stanford (q.v.), as a memorial to their only son who died

LELAND STANFORD JR. UNIVERSITY

in his 16th year. The founders desired that the University should give a training primarily fitted to the needs of young men. Both sexes are admitted to equal advantages in the institution, but the number of young women who may attend at any given time is limited to 500. The object of the University as stated by its founders is "to qualify students for personal success and direct usefulness in life," and to "promote the public welfare by exercising an influence in behalf of humanity and civilization, teaching the blessings of liberty regulated by law, and inculcating love and reverence for the great principles of government as derived from the inalienable rights of man to life, liberty and the pursuit of happiness."

The endowment grant establishing the University was made in November 1885, under an act of legislature passed for this purpose; the cornerstone of the institution was laid in May 1887; and the University was formally opened to students on 1 Oct. 1891. The attendance for the first year numbered 559 and included all college classes with a number of graduate students, the University graduating its first class of 38 in May 1892. The original faculty numbered 35 professors and instructors and the first, and to the present time (1903) the only, president has been David Starr Jordan (q.v.).

The architecture of the University buildings is patterned after the old Spanish missions of California and Mexico. The buildings are of buff sandstone with red tile roofs. They form two quadrangles, one within another, with detached buildings grouped about them. The inner quadrangle consists of 12 one-story buildings, connected by an open arcade, facing a paved court of three and one quarter acres in extent. Connected with this quadrangle at various points by corridors, and completely surrounding it, is the outer quadrangle of 12 buildings, for the most part two stories in height above the basement. This outer quadrangle is again surrounded by a continuous open arcade. In the inner quadrangle are the departments of law, of the different languages, and mathematics, and the administrative offices. In the outer quadrangle are the scientific, engineering and geological departments, those of history, economics and English, and the library and assembly hall. In the rear of the quadrangles are the central lighting, heating and power plant and the laboratories and shops of the engineering departments. The dormitories, one for young men and another for young women, with their gymnasiums and athletic grounds about them, are located to the east and west. In front on either side of the main drive are the buildings for the department of chemistry and the art museum and the new gymnasium, the latter in course of erection. The final building to complete the general scheme of buildings, which is to be the permanent home of the University library, will soon be begun.

Most striking among the architectural features of the University buildings are the Memorial Arch and the Memorial Church. The former is 100 feet in height, 90 feet in width and 34 feet deep, with an archway of 44 feet spanning the main entrance. A sculptured frieze 12 feet in height, designed by St. Gaudens, and representing the progress of civilization, surrounds the arch. The Memorial Church opens from the inner court and is opposite the

main entrance. It is of Moorish-Romanesque architecture, its spire rising to a height of 188 feet. The church, erected by Mrs. Stanford in memory of her husband, is adorned within and without with costly mosaics, representing as do the beautiful stained windows, Biblical scenes and characters. It has a splendid organ of 46 stops and 3,000 pipes and a chime of sweet-toned bells. The church is non-sectarian in character and method. Religious services are held each Sunday morning and afternoon. There is a week-day vesper service and the organ is played each day at the close of recitations.

The students live in the dormitories, in club houses on the grounds, or in private boarding-houses in the village, which is situated a mile distant from the University buildings. The professors live in homes provided on the grounds or in the village. Twelve Greek-letter societies for young men and five for young women occupy chapter homes on the campus.

In the government of the students, "the largest liberty consistent with good work and good order is allowed. They are expected to show both within and without the University such respect for order, morality, personal honor, and the rights of others as is demanded of good citizens. Students failing in these respects or unable or unwilling to do serious work toward some definite aim are not welcomed and are quickly dismissed."

The University Council consists of the president, professors, and associate professors of the University faculty. To it is entrusted the determination of requirements for admission, graduation, and other matters relating to the educational policies of the institution. It acts as an advisory body on questions submitted to it by the president or trustees. The routine work of the faculty is divided among various standing committees with power to act and responsible primarily to the president. Departmental affairs are in the hands of subordinate councils consisting of the instructing body in the department, a member of which is designated by the president as presiding officer.

The general control of the University's affairs was by special provision in its charter reserved to the founders or either of them during their lifetime, they to act in the capacity of a board of trustees, the trustees themselves having only a nominal connection. This provision remained in force until July 1903, when under a special act of legislature passed for the purpose, Mrs. Stanford finally turned over to the board of trustees full authority and control over the University. The board of trustees numbers 15, members being elected for a term of 10 years. In educational matters the president of the University has the initiative, his acts being subject to the confirmation of the trustees. The board through a treasurer and business manager, one of their own number, administers directly the financial affairs of the institution.

The endowment of the University comprises 90,000 acres of land, including the Palo Alto estate; the Stanford home in the city of San Francisco, and interest-bearing securities, the whole amounting to about \$30,000,000, two-thirds of which is productive of income. For the present the income of the University is devoted largely to the completion of its buildings.

In its entrance requirements the University

LELAND UNIVERSITY—LEMARS

recognizes 29 entrance subjects of different values according to the time devoted to them in the secondary schools. The unit of value is a full year of high school work in the particular subject, and any 15 units, with certain limitations, chosen from this list constitutes preparation for full entrance standing. The University has no list of accredited schools, but considers on its merits the work of all reputable schools. The student chooses a major subject, the professor in which becomes his adviser and to which he is required to devote one fourth of his time. His remaining time is filled up by courses chosen by the student under the advice and direction of his major professor. Fifteen hours of recitations per week constitutes the regular course throughout a period of four years. Students are graduated when they have completed 120 hours of work and the requirements of their major subject. Degrees are conferred in May, September, and January.

The University grants the undergraduate degree of A. B. in all courses; the degrees of A. M. and Ph. D. for one, and three years' work respectively beyond the undergraduate requirements; the LL. B. degree in law, and that of Engineer for graduate work. The University grants no honorary degrees.

The work of the University is grouped under the following departmental heads:

Greek, Latin, Germanic Languages, Romanic Languages, English Language and Literature, Philosophy, Psychology, Education, History, Economics and Social Science, Law, Drawing, Mathematics, Physics, Chemistry, Botany, Physiology and Hygiene, Zoology, Geology and Mining, Civil Engineering, Mechanical Engineering, Electrical Engineering.

The University Library contains 75,000 volumes. The attendance for the year 1902-3 was 1,483, of which 998 were men, 485 women. The faculty numbers 130. Tuition is free to California students. Those from other States pay a registration fee of \$10 per semester.

GEORGE A. CLARK,
Secretary of the University.

Leland University, a Baptist institution for the education of the colored people; founded in 1869, in New Orleans, La., by Holbrook Chamberlain of Brooklyn, N. Y. It has large grounds, commodious and well equipped buildings, and a fair endowment. It is a school and a system of schools, with a faculty of over 60 members and co-ordinated courses of study. It is made up of a number of academies, each built and maintained by one of the 15 Baptist Associations in the State. The courses consist of the usual work of the elementary and secondary schools, including a preparatory department where pupils are fitted for college. In addition are a college, a theological department, training classes for pastors and teachers, and departments of manual training, domestic science, and agriculture. Dr. R. W. Perkins is president (1903), and the board of trustees is made up of prominent citizens of New Orleans, La., and Brooklyn, N. Y. The number of students in 1903 was over 2,000.

E. R. W. PERKINS,
Leland University.

Le Loutre, Louis Joseph, 100-é zhō-zéf lē lootr, French missionary: b. about 1692; d. about 1775. He was vicar-general of Acadia,

and from about 1740, when he was sent to Nova Scotia, he labored for years among the Micmac Indians of that region with great success, obtaining practical control of all their affairs, spiritual and otherwise. He led them against the English, and when the country fell into the hands of Great Britain succeeded in compelling the Acadians to show their allegiance to King Louis, although for years they had been subjects of King George. The consequence was terrible suffering for the simple people, whose miseries became historic through their deportation in 1775. Le Loutre fled to Quebec, sailed for France, was taken by the English and kept prisoner in the Isle of Jersey for eight years. Being released, he returned to France, where he died.

Lely, lē'lī, SIR Peter, Dutch painter: b. Soest, Westphalia, 1618; d. London 30 Nov. 1680. His real name was Pieter van der Faes, but he assumed as his artistic title a nickname, Lely, or rather Le lys, which had been borne by his father. He was the pupil of Peter Grebber in his early manhood, but went to England in his 23d year and began his career as a portrait painter. His pictures were much admired and Charles I. appointed him court painter. He painted the portrait of that sovereign and also of Cromwell, but he reached his greatest eminence after the Restoration. He was an imitator of Van Dyck, whom he almost equaled in the excellence of some of his earlier work. But as he fell in with the artificiality of Charles II.'s licentious court his manner lost much of its dignity and originality, and with a fatal facility he assumed that mannerism which detracts so much from the artistic worth of his portraits. His coloring as well as his drawing became weak and conventional. He was, however, a great favorite with the king and his famous "Beauties of Hampton Court" was painted at the request of his royal master, these "beauties" being the loveliest women of the court, including the Duchess of Cleveland. Lely founded the school of English portrait, and up to the time of Reynolds and Lawrence was its ablest representative. His method of handling, as well as his conception of the portrait, were long imitated, and even to-day have their influence.

Lemaître, Jules, zhül lē-mātr, French critic: b. Vennecy, Loiret, 27 April 1853. He was a teacher in various schools, and a professor at Grenoble in 1883-4. He then resigned his post and entered on a successful literary career at Paris. Though he wrote two books of verse and three of short stories, he won his position in French letters by his criticism, his essays having associated him with Brunetière as a representative figure. "Impressions du Théâtre" (1888 et seq.), and "Contemporains" (1886 et seq.) collect the best of his articles. His dramas, such as "Député Leveau" (1891), "Les Rois" (1893), and "Le Pardon" (1895), have also been much approved.

Léman, lā-mān, Lake, a name sometimes given to the Lake of Geneva. See GENEVA, LAKE OF.

Lemars, lē-märz', Iowa, city, county-seat of Plymouth County; on the Chicago, St. P., M. & O., and the Illinois C. R.R.'s; about 155 miles northwest of Des Moines, the capital of the State, and 24 miles north by east of Sioux

LEMBERG—LEMMING

City. It is situated in an agricultural region in which cattle, wheat and corn are raised extensively. The chief manufactures are foundry and machine-shop products, flour, brick, blank books, and dairy products. It has a public library. Lemars is the seat of the Western Union College, under the auspices of the United Evangelicals. Pop. (1900) 4,146.

Lemberg, lém'bérg, Austria, the capital of the crownland of Galicia, on the Peltew, 365 miles by rail northeast of Vienna. Founded in the 13th century and formerly surrounded by walls, the city notwithstanding has a modern appearance, the walls having been replaced by boulevards and promenades. It is the seat of the crownland government, and of the important courts and public offices connected with it, also of three metropolitan sees, Greek, Armenian, and Roman Catholic, with their cathedrals and establishments. The university founded in 1784 and reorganized in 1817 is attended by about 2,000 students, and has a library of over 86,000 volumes. The National Institute founded in 1817 by Ossolinsk has a library of over 80,000 volumes and 3,000 MSS. chiefly of Polish literature. The manufactures are extensive and varied, and there is a large trade, mostly in the hands of Jews. The heterogeneous population consisting of Jews (over 31,000), Poles, Ruthenians, and Germans, was (1900) 159,618.

Lémery, lám-ré, Nicolas, French chemist: b. Rouen 17 Nov. 1645; d. Paris 19 June 1715. At an early age he displayed a taste for chemistry, went to Paris in 1666, and attached himself to Glaser. He soon left Glaser and took up his abode at Montpellier, where he had the free use of a laboratory, and began to give lectures which excited great interest and were attended by many of the influential inhabitants of the place. In 1672 he returned to Paris and gave courses of lectures on various parts of chemistry, the success of which seems to have been very great. His 'Cours de Chimie' appeared in 1675. This book went through numerous editions—31, it has been calculated—and was translated into the chief European languages. The book is plainly modeled upon the prior treatises of Lefebvre and Glaser, the opening chapters being identical in manner and treatment, but shows proof of the author having profited by the work of his predecessors. In 1681 the religious troubles began to harass him; he was required to demit his office by a given time, and had ultimately, in 1683, to take shelter in England, where he was well received by Charles II., to whom he dedicated an edition of his book. He returned later to France, graduated as doctor of medicine at Caen, went to Paris, where he soon had a very large practice; but in 1685 the revocation of the Edict of Nantes forbade him, as a Protestant, the exercise of this profession. Against this he struggled for a little, but in 1686 joined the Roman Catholic Church. In 1699 he became an associate of the Academy of Sciences. Besides the 'Course of Chemistry,' Lémery wrote and published other works and papers, among which may be mentioned: 'Pharmacopée universelle' (1697); 'Traité universelle des Drogues simples' (1698); 'Traité l'Antimoine' (1707). It deserves to be remembered that he was one of the first to attempt the elucidation of natural terrestrial phenomena by referring them to chemical action, and to ex-

hibit these on an experimental scale, as when he made what is still known as Lémery's volcano, by placing a mixture of sulphur and iron in a hollow, heaping up the earth over the mixture, moistening, and leaving it to itself. By-and-by combination between the iron and sulphur begins, heat is evolved, the earth heaves and swells, steam escapes, and the resemblance of the miniature eruption to the larger original is very striking. He left two sons, both of whom were afterward distinguished as chemists.

Lem'ly, Henry Rowan, American soldier: b. North Carolina 12 Jan. 1851. He was graduated from West Point in 1872, and was appointed 2d lieutenant of the 3d cavalry. In March 1898 he was promoted captain, and during the Spanish-American War commanded Battery C of the 7th United States Artillery in the Porto Rico campaign. He was retired at his own request 20 April 1899. He has published 'What Was El Dorado?'; 'Among the Arapahoes'; 'West Point Romance'; 'Padre Anselmo'; 'A Queen's Thoughts'; etc.

Lemly, Samuel Conrad, American naval officer: b. Salem, N. C., 14 March 1853. He was graduated at the United States Naval Academy in 1873; was promoted lieutenant in January 1886; and in 1892 was appointed judge advocate-general of the navy. He was reappointed in 1896 and 1900, and in 1901 was the legal representative of the navy in the Schley Court of Inquiry.

Lem'ming, a short-tailed rat-like animal, related to the European voles and American meadow-mice, which inhabits the high mountains of Scandinavia. Its technical name is *Myodes lemmus*, and closely related species are found in northern Siberia and in Arctic America. In general appearance these animals are more like miniature short-eared, yellowish rabbits or pikas than like mice; they subsist wholly upon vegetable food, dwell in nests made of bark, grass, etc., in some sheltered nook, and do not hibernate but force their way about underneath the snow in search of moss, lichens, sprouting woody plants and other edible things. They are very prolific, rearing two broods of four to six young annually, and hence every few years they become so numerous that the mountains can no longer support the hordes. At such times, occurring at irregular intervals of several years according to circumstances, an exodus takes place, and great numbers of lemmings descend from the mountains and spread over the lowlands. There the easier climate, more abundant food and absence of enemies, permit a still further multiplication, so that by the following season the little animals have increased into a plague. They wander more and more widely, overrun and damage, or sometimes wholly devour crops, gardens and meadows, and make themselves a destructive nuisance. Such an invasion is felt more severely in the narrow and fertile valleys of Norway than in the broader and more forested spaces of Sweden. At such a time concerted measures are devised to kill them off, carnivorous mammals and birds flock to the feast, and epidemic diseases often break out among them. Spreading with a restless energy for travel, the lemmings overcome or attempt to overcome all obstacles, and heedlessly plunge into lakes too large or rivers too swift to be crossed. When

LEMMING-MICE — LEMON OIL

the remnants of the host reach the sea many of them boldly swim out in their ignorance of its magnitude and are drowned. Such overrunning of the country by lemmings is not known in Arctic Asia or America, where different conditions exist.

Lemming-mice, certain small mice-like animals closely related to the lemmings and having similar traits, inhabit the region about Hudson Bay and the southern part of Greenland, of which the most prominent is *Cuniculus torquatus*, chiefly remarkable for its turning white in winter. Other species belong to the genera *Synaptomys*, *Lemmus*, etc.

Lem'mon, John Gill, American botanist: b. Lima, Mich., 2 Jan. 1832. He studied at the University of Michigan, but left to enter the Federal army in June 1862, and was a prisoner at Andersonville, Ga., from August 1864, till the end of the Civil War. He has lived in California from 1866, where he was for four years botanist of the State Board of Forestry. He has published 'Recollections of Rebel Prisons' (1874); 'Ferns of the Pacific Slope' (1884); 'Handbook of North American Cone Bearers' (1895); 'Botanizing in Apache Land' (1901); 'How to Tell the Trees' (1902); etc.

Lem'nian Earth, a reddish earth found in the island of Lemnos, celebrated as a remedy for snake-bites and various diseases, and collected by the ancients in accordance with special religious observances on only one day in the year. Analysis shows it to be composed of silica, 67 per cent; alumina, 14 per cent; water, 8 per cent; iron oxide, 5 or 6 per cent; soda, about 3 per cent, and traces of lime and magnesia. Its classical name "terra sigillata" (sealed earth) is due to the fact that it was compressed and marked with the head of the Lemnian Diana. The earth is a fair substitute for soap, but has no medicinal properties.

Lem'nos, the classical name for STALIMENE, the northernmost island of the Grecian archipelago, between the Hellespont and Mount Athos. It anciently contained a volcano, Mosychlus, which was regarded as the workshop of Hephaestos (Vulcan), and was worshipped by the Greeks as sacred. The island belongs to Turkey and consists of two peninsulas almost separated by the harbors of Paradiso and San Antonio. It has an area of 160 square miles, and abounds in vineyards, wheatfields, olive and fruit groves. The chief town is Limno or Kastro, with 3,000 inhabitants, a fortified place on the west coast. Pop., chiefly Greeks (1903) 27,000.

Le Moine, lē-moin', Sir James MacPherson, Canadian historian: b. Quebec 24 Jan. 1825. He was educated in his native city and in 1850 was called to the bar. In 1869 he was appointed inspector of the inland revenue district of Quebec. He was knighted in 1897. Among his works are: 'L'Ornithologie du Canada' (1860); 'Étude sur les Navigateurs Arctiques Franklin, McClure, Kane, McClintock' (1862); 'The Tourist's Note-Book' (1870); 'Quebec: Past and Present' (1876); 'The Scot in New France' (1880); 'Picturesque Quebec' (1882); 'The Land We Live In' (1891).

Lemon, Mark, English humorist and playwright: b. London 30 Nov. 1809; d. Crawley, Sussex, 23 May 1870. He made his first es-

says in the lighter drama, and the modern London stage was supplied by his facile pen with more than 60 pieces, farces, melodramas, and comedies, among which were: 'The School for Tigers,' 'The Serious Family,' and 'The Ladies' Club.' On the establishment of 'Punch' in 1841 he became joint editor with Henry Mayhew, and two years later, sole editor, controlling that periodical for 29 years. He was also literary editor of, and frequent contributor to, the 'Illustrated London News.' Among his later productions are several novels: 'Loved at Last,' 'Golden Fetters,' etc. He also edit'd 'Mark Lemon's Jest Book.'

Lemon, a small tree or spreading shrub (*Citrus medica* var. *limon*) of the natural order *Rutaceæ*. It is a native of India, but has been introduced into tropical and subtropical countries throughout the world, especially those of the Mediterranean region, whence it was imported into Florida and California. In Florida the cold wave of 1894-5 destroyed most of the orchards, leaving only those in the southernmost counties, the soil of which is poorly adapted to the trees and must be carefully mulched, fertilized and managed to yield profitable returns. In California the lemon was introduced about 1850, but did not become commercially important until the closing quarter of the 19th century, during the last ten years of which the annual shipments to eastern markets averaged about 1,200 carloads, although half of the 400,000 trees had not yet reached bearing age. The climate is perfect, but the water supply is deficient, so that the orchards must be irrigated. The fruit is one of the most important grown in the United States, since in addition to its value in food drink, the citric acid of its juice is used upon a commercial scale by calico-printers, who by its aid remove iron from patterns stamped with certain dyes; and the oil or extract distilled from the rind is serviceable in perfumery, for flavoring, etc.

Owing to its spreading habit the tree must be carefully pruned, else it will make the necessary cultivation impossible and will result in bearing fruit at or near the ends of long willowy branches. The trees are usually set about 20 feet apart each way, given clean cultivation and fertilization like the orange (q.v.). The fruit, which ripens during the winter is cut, not pulled, green as soon as it is two and one quarter inches in diameter, the picker carrying a gauge. These details have been found necessary since lemons ripened on the tree are of inferior quality and will not keep well, and since the market demands lemons in the summer. The fruit is spread in shallow trays and stored in a well ventilated curing house where by careful management it develops the characteristic yellow skin, which also becomes tougher, thinner, more pliable and silky and less liable to injury in handling. When properly managed, lemons are profitable, and because of the constant demand are more reliable than any other of the citrus fruits.

Lemon Oil, a volatile oil obtained, by pressure, from lemon peel. It consists chiefly of a terpene, $C_{10}H_{16}$, known as limonene, which boils at 349° F., and closely resembles citrene, though differing from it in certain essential particulars. Lemon oil has an agreeable odor, and is used chiefly as a flavor and perfume. It is reputed to change spontaneously into turpentine

LEMON VINE—LE MOYNE

upon keeping, but this belief probably has no foundation in fact. Lemon oil mixes in all proportions with glacial acetic acid and with absolute alcohol.

Lemon Vine. See BARBADOS GOOSEBERRY.

Le Moine, Antoine, än-twän le-mwän, SIEUR DE CHÂTEAUGUAY, French soldier and colonist in America: b. Montreal 7 July 1683; d. Rochefort, France, 21 March 1747. He was a son of Charles Le Moine (1626-85) (q.v.). He entered the French army, and in 1704 came to Louisiana with a company of settlers. In 1705-6 he fought under D'Iberville against the English, in 1717 was appointed commandant of the French forces in Louisiana, and in 1718 king's lieutenant of that colony. With the aid of Indians he captured Pensacola from the Spanish 14 May 1719; but he surrendered it 7 August. Having been held as a prisoner of war until July 1720, he took command at Mobile upon the conclusion of the peace of that year, but returned to France in 1726. He was governor of Martinique in 1727-44, and from 1745 of Cape Breton.

Le Moine, Charles, shärl, SIEUR DE LONGUEUIL, French settler, soldier, and proprietor in America: b. Dieppe, France, 1626; d. Villemarie, Canada, 1685. He came to Canada in 1641, settled at Villemarie, and was interpreter between the Hurons and the colonists. In 1651 he successfully defended the fort from an attack by the Iroquois, whom he routed with great slaughter; and in 1653 he concluded a peace with the Five Nations. These Indians, however, in 1655 again made an attack upon the colony, which was saved from destruction largely by Le Moine's exertions. In 1657 Le Moine received from François de Lauzon, who held 60 leagues of land under royal grant, full seigniorial rights; and in 1664 his possessions were largely increased by the cession of Isle St. Hélène and other tracts. He participated in the expedition led by Tracy and Courcelles in 1666-7, and in several campaigns against the Iroquois; and for many years was captain of Montreal. He was made Sieur de Longueuil in 1668, and to this title that of Châteauguay was later added.

Le Moine, Charles, 1ST BARON DE LONGUEUIL, French soldier in America: b. Villemarie, Canada, 10 Dec. 1656; d. there 8 June 1729. He was a son of Charles Le Moine (1626-85) (q.v.). He entered the French army, with which he served in Flanders, but returned in 1683 to Canada, where he became mayor of Montreal. He promoted colonization in Canada, and built a stone fort on his estates at Longueuil. In the campaign of 1687 against the Iroquois he was commander of a division of militia; and in 1690 he was wounded at the repulse of Phipps' attack on Quebec. He was made baron and governor of Montreal in 1700 for services to the colony; commanded the Canadian forces at Chambly, when the English made an unsuccessful attempt to take Montreal; and in 1711 became commander-in-chief of the colonial troops. He commanded at Three Rivers in 1720, and was again governor of Montreal in 1724-6. In 1726 he rebuilt Fort Niagara.

Le Moine, Jacques, zhäk, SIEUR DE SAINTE HÉLÈNE, French soldier in America: b. Villemarie, Canada, 16 April 1659; d. Quebec October 1690. He was a son of Charles Le Moine (1626-85) (q.v.). In March 1686 he accom-

panied the expedition led by the Chevalier de Troyes against the English on Hudson Bay, and in the capture of Forts Rupert, Monsipi, and Quitchitchonéen, and the seizure of the English governor-general, took a prominent part. He was second in command of the expedition that captured, plundered and burned Fort Corlear (now Schenectady) 9 Feb. 1690. In October Phipps laid siege to Quebec, and Le Moine was selected to direct the defense. He was mortally wounded while leading about 200 troops in the repulse of 1,300 British at the passage of the St. Charles.

Le Moine, Jean Baptiste, zhöñ báp-tëst, SIEUR DE BIENVILLE, French administrator in America: b. Villemarie, Canada, 23 Feb. 1680; d. Paris 1768. He was a son of Charles Le Moine (1626-85) (q.v.). In 1691, upon the death of his brother, Charles, Baron de Longueuil (q.v.), he succeeded to the title; but he was known as De Bienville. In 1697 he served in the expedition of the Chevalier de Troyes against the English settlers in Hudson Bay. He afterward went with his brother, D'Iberville (see IBERVILLE) to France, and 24 Oct. 1698, sailed from Brest in the expedition led by D'Iberville to take possession of the mouth of the Mississippi. Bienville was appointed lieutenant of the king, explored the surrounding region, and in 1700 became commander of a fort on the river 44 miles above its mouth. He succeeded Sauvole in the direction of the colony, and assumed command of the camp of Biloxi 22 Aug. 1701. In December he transferred the settlement to Mobile, which prospered through the arrival of recruits from France with supplies (1703-4) and of 50 Canadians (1706). In February 1708 he was ordered to France as a prisoner, but he was later reinstated. The attempt to cultivate the soil by Indian labor having been unsuccessful, he suggested to the king in 1708 the importation of negroes from the Antilles, to be exchanged for Indians at the rate of three Indians for two negroes. In 1713 Cadillac arrived as governor, and Bienville was commissioned lieutenant-governor. Bienville led an expedition to the territory of the Natchez Indians in 1716, built a fort, and concluded a treaty. In 1718 he became governor of Louisiana, in the same year founded New Orleans, which was made the seat of government in 1723, in 1724 went to France to answer charges preferred against him, but in 1733 returned as governor with lieutenant-colonel's rank. After unsuccessful campaigns against the Chickasaws in 1736, 1739, and 1740, he sailed for France in 1743.

Le Moine, Joseph, zhözëf, SIEUR DE SÉRIGNY, French soldier in America: b. Villemarie, Canada, 22 July 1668; d. Rochefort, France, 1734. He was a son of Charles Le Moine (1626-85) (q.v.). He entered the French navy, and in 1694 and 1697 commanded the flotilla which co-operated with his brother, D'Iberville (see IBERVILLE) in the expedition to seize Hudson Bay. Later he received command of a squadron, took to Louisiana Canadian settlers, and surveyed (1718-9) the coast of that colony. He drove the Spaniards from their fortifications at Pensacola (15 June 1719), and repulsed them at Dauphin Island, near Mobile (19 August); became a captain in 1720; and in 1723 rear-admiral. From 1723 he was governor of Rochefort.

LE MOYNE—LEMURS

Le Moyne, Paul, pôl, SIEUR DE MARICOURT, French soldier in America: b. Villemarie, Canada 15 Dec. 1663; d. there 21 March 1704. He was a son of Charles Le Moyne (1626–85) (q.v.). He participated in Troyes' expedition against the English at Hudson Bay, was wounded in the attack on Fort Monsipi (20 June 1686), and remained with his brother D'Iberville (see IBERVILLE) in command of the captured district until 1690. In 1690 he distinguished himself in the defense of Quebec against Phipps, later took part in Frontenac's expedition against the Iroquois, and in 1701 concluded peace with them.

Le Moyne, Paul Joseph, pôl zhō-zéf, CHEVALIER DE LONGUEUIL, French soldier in America: b. Canada 17 Sept. 1701; d. France 12 May 1778. He was the son of Charles Le Moyne (1656–1729) (q.v.). He entered the French army in 1718. He commanded at Fort Frontenac, and was also governor successively of Detroit, Three Rivers, and Quebec. He fought with distinction in various campaigns, and in 1747 marched 180 miles in the depth of a severe northern winter to reinforce de Vaudreuil at the siege of Fort George.

Le Moyne, Pierre. See IBERVILLE, PIERRE LE MOYNE SIEUR D'.

Lempa, lém'pä, San Salvador, a river, the largest of Central America, which rises in Lake Guija on the boundary of Guatemala and San Salvador, flows eastward through a broad and fertile valley for a distance of nearly 150 miles, and then turning abruptly to the south breaks through the volcanic coast range of mountains, and finishes its course of over 200 miles in the Pacific in lat. 13° 12' N., lon. 88° 41' W., 35 miles southeast of San Salvador City. It has numerous large tributaries and is subject to sudden floods. The mouth of the river is obstructed by a bar, but the river is reached by a natural channel connected with the Jaltepeque estuary, and is navigable by small steamers for 100 miles.

Lemprière, John, English classical scholar: b. island of Jersey about 1765; d. London 1 Feb. 1824. He was graduated at Oxford University in 1790, was ordained and began life as a schoolmaster. He afterward was appointed to the livings of Mesth (1811), and Newton-Petrock (1823). He is the author of the well-known classical dictionary (1788), which was founded on Sabatier's 'Dictionnaire des Auteurs Classiques.' He also published: 'Sermons' (1791); 'Translation of Herodotus,' first volume only (1792); and 'Dictionary of Universal Biography' (1808).

Lemures, lem'ū-rēz, among the ancient Romans, a term applied to departed spirits, especially those of ancestors who hovered about during the night. Probably the word was derived from the festival *Lemuria* held 9, 11 and 13 May, when at midnight the father of the family, with special ceremonies, nine times threw black beans over his head, thus banishing the spirits from the household for another year.

Lemu'ria, a name given by Haeckel to a vast area assumed to exist in past ages over the area of the present Africa, Indian Ocean and Malayan archipelago, on the hypothesis that the existence of such a continent was necessary to explain the peculiar present distribution of the lemurs and other phenomena of geographical

distribution. The discovery of the remains of lemurs in America and Europe rendered such hypothesis futile, and the idea was soon abandoned. Consult: Wallace, 'Geographical Distribution of Animals' (1876).

Lemurs, lē'mérz, the curious monkey-like animals, or "half-apes" forming the group *Lemuroidea* within the order Primates, where they stand lowest in rank. They are divisible into three families, *Lemuridae*, *Tarsiidae* and *Chiromyidae*. The last contains only the aye-aye (q.v.); and the second only the Malayan tarsiers (q.v.). The lemurs proper (*Lemuridae*) are confined mainly to Madagascar, but a few are found upon the African continent, and a few others, of peculiar genera, in the Oriental region. They are chiefly arboreal, and more squirrel-like than monkey-like in their manners, and quite harmless, gentle and tamable. They are usually mouse-gray or yellowish, not marked in ornamental ways, the hair is long and often woolly, and the tail usually long, bushy and never prehensile. The hind-legs are longer than the fore-legs in the true lemurs, which move about on all fours, not using their hands as do monkeys, although the thumbs are opposable; the second toe always has a sharp claw, while the other digits bear nails. In the internal anatomy many features are different from the rule of structure elsewhere in the order. The simplicity of the brain, the fact that certain arteries form retia mirabilia, and especially the nondeciduate condition of the placenta, are prominent among these lemuroid peculiarities. In general, however, the lemurs show much resemblance to the *Anthropoidea*.

The *Lemuridae*, or lemurs proper, are divisible into four groups or sub-families. The first group (*Indrisinae*) is limited to Madagascar, and includes several genera distinguished prominently by the great size of the hind-legs, as compared with the fore-limbs; and when upon the ground these lemurs walk erect, balancing themselves by holding their short arms above their heads. The largest is the indri (q.v.), which has no visible tail, while the smallest are the avahis (genus *Avahis*) which are the size of gray squirrels, but have very long tails. A third important genus is *Propithecus*, containing several large brightly colored species, called sifakas, which are mainly vegetarian, go about in large bands like the indris, and seek food in the daytime, whereas the avahis are nocturnal; and are often tamed and taught to hunt like dogs.

The most typical lemurs are in the sub-family *Lemurinae*, which contains several genera, some of which inhabit the Comoro Islands as well as Madagascar. Their limbs are of nearly equal length, and they have a fuller dentition (36 teeth). Among the best known are the so-called "gentle" lemurs; the nocturnal grass-eating bokomboulis (*Hapalemur*); and the handsome and highly arboreal species of the type-genus *Lemur*, which vary greatly in habits, food and appearance. One of these is familiar as the "Madagascar cat" or ring-tailed lemur (*L. catta*), since, unlike the rest, it remains upon the ground, especially about rocks, is easily caught and readily tamed. It is remarkable for the fact that the sexes differ in color, the male being black, while the female is reddish brown with white whiskers and ear-tufts, and the tail alternately ringed with brown and white. The

LENA — LENBACH

ruffed lemur (*L. varius*) is still more strikingly diversified in black and white, and has a ruff of long hair about the neck. All these lemurs survive captivity well and furnish interesting specimens for all zoological gardens.

The third sub-family is that of the *Galaginae*, represented in the continent of Africa and in Madagascar. The galagos (q.v.) have long hind-legs, causing them to hop like kangaroos, when on the ground (but the most of their life is passed in trees), large, semi-naked ears and long tails. Important genera are *Galago* (q.v.); the mouse-lemurs or chirogales (q.v.); and the diminutive squirrel-like dwarf-lemurs (*Microcebus*).

The sub-family *Lorisinae* contains a group of small lemurs, distributed widely in Africa, India, and Malaysia. "In external appearance," remarks Beddard, "all the three genera of this sub-family agree in their small size, their short or entirely deficient tail, large staring eyes, and the rudimentary character, or absence, of the index finger, which is never provided with a nail; in all of them the thumb diverges widely from the other fingers, and the great toe is so divergent as to be directed backward." The ears are small and rounded; and the eyes are very large, and situated close together on the front of the head. They feed on small birds and insects, and are chiefly nocturnal in habits. They inhabit India, Ceylon, and the Eastern Archipelago. The genus *Nycticebus* contains the remarkable "sloth monkey" or sloth lemur (*N. tardigradus*), which is nocturnal, howls dismally at times, and is the object of many fears and superstitions among the Malays and southern Chinese. The genus *Perodicticus* contains the queer African pottos and angwantibos (q.v.). The most typical species of the group is the slender loris (*Loris gracilis*), a pretty little arboreal animal of the Malayan countries, and the subject of many fears and curious superstitions among the Malays and southern Chinese.

The geographical and geological distribution of the lemurs is very interesting. Their remains are found in the rocks as far back as the transition period (Puerto beds) between the Cretaceous and Tertiary, the oldest occurring in the western United States. These are small lemuroids, and similar forms are found in the early Tertiary rocks of Europe, Asia, and Africa. Many genera are known. The most recent, which may have survived in Madagascar until the discovery of that island by Europeans, was *Megaladapis*, which must have been three or four times bigger than any modern species. The circumstance that existing lemurs and certain other animals occur only in south-central Africa, Madagascar and the Oriental region, and nowhere between, was so extraordinary a fact in zoogeography that early attempts to account for it resulted in the hypothesis of an ancient continental land-area, called *Lemuria* (q.v.) which was supposed to connect Africa and southern Asia. This theory had little other foundation, and the subsequent discovery of remains of extinct lemurs in Europe, Western Asia, and the two Americas, showed that it was needless. It is evident that the existing lemurs are the survivors of a once world-wide race which has died out except in certain islands and favorable corners of the world where they are not exposed to cold climates nor to too many enemies. The

almost complete absence of predatory animals in Madagascar doubtless explains the comparatively great number of lemurs characteristic of that isolated country.

Consult: Beddard, 'Mammalia' (1902); Forbes 'Allen's Naturalists' Library' (1894); Lydekker, 'Royal Natural History,' Vol. I., (1893); Mivart and Murie 'Anatomy of the Lemuroidea,' in Trans.-Zool. Soc. of London, Vol. VII. (1872).

Lena, lä-nä' or lē'na, Siberia, one of the largest rivers in the world, rising on the north-western side of the mountains which skirt the western shore of Lake Baikal, about 170 miles east-northeast of Irkutsk. It flows in a winding course, north-northeast and northwest, receiving the Vitim, the Aldan, the Viliui, and other tributaries. Then a mighty stream it flows generally north, till, separating into branches, it forms a great number of deltaic islands, and discharges itself into the Arctic Ocean by several mouths, in lat. 73° N., and lon. about 128° E., having thus passed over 21° of lat. and 22° of lon. Its direct course, through a generally barren country interspersed with a few dense forests, is about 1,480 miles; its actual course, windings included, about 2,770 miles. It is navigable through the greater part of its course, but is frozen from October to May.

Lenapé (lēn'a-pā) Stone, in archaeology, a name given by H. C. Mercer to an inscribed gorget, upon which was incised a spirited combat between men and a mastodon; lightning intervening and aiding the men in the destruction of the beast. The stone told pictorially the legend recorded by Jefferson in his 'Notes on Virginia.' Since its discovery the stone has been condemned by most archaeologists, and not always on the same grounds, and it is probable that it will not be accepted generally as genuine until abundant corroborative evidence has been obtained. If genuine, the stone establishes two most interesting facts concerning the Indians of the Atlantic seaboard; that the mastodon or mammoth was living when these people were at the climax of their cultural development, or, if not a feature of practically our present fauna, then that the advanced Indian lived at a much more remote period than is generally supposed. The evidence now had concerning the mastodon is that it was living about 2,500 years ago, and this antedates the Indian as so advanced an occupant of this region. That man has been an occupant of our seaboard region since the Glacial Epoch is demonstrable, and his contemporaneity with so recently extinct an animal as the mastodon is certain. The principal objection that can be brought against its genuineness is that it is so far in advance of all other known specimens of Indian pictographic art.

C. C. ABBOT.

Lenbach, Franz von, fränts fōn lēn'bāh, German painter: b. Schrobenhausen, Upper Bavaria, 13 Dec. 1836; d. Munich 19 May 1904. He began life as a bricklayer, but at the suggestion of Hofner, the animal painter, turned to the study of art, and became a pupil of Geyer in Augsburg. He subsequently attended the Munich Academy for a short time, and then for two years studied the technique of painting under Gräfe. From 1855 to 1857 he lived as one of the artistic coterie of

LENCLOS — L'ENFANT

Schrobenhausen, and painted portraits, landscapes, and animals. He then attached himself to Piloty, and as the pupil of that artist accompanied him to Rome. Here he applied himself to the study of the old masters and painted his picture 'The Roman Forum,' whose vivid coloring and grandeur of design made his reputation. After his return to Germany he painted several portraits, which were distinguished by a power of coloring rivaling that of the Venetian school, and a vivid characterization and chiaroscuro which recalled Rembrandt. He was for a few years teacher in the Weimar school of art, but eventually returned to Munich, and attracted the attention of Baron von Schack, who engaged him to visit Italy and Spain for the purpose of making copies of the principal paintings of Giorgione, Velasquez, Titian, Rubens and others. The copies executed by the painter have all the individual tone and color of each original, and he developed immensely his own power and style by their production. This appears most plainly from an examination of his portraits which, original and fresh as they are, show plainly that the master had trained himself in the school of Titian, Rembrandt and Velasquez. Though his drawing is sometimes weak and incorrect, his paintings nevertheless are characterized by powerful modeling, life-like expression, and as a portrait painter he sees to the soul of his sitter with genial and sympathetic intuition. Since his 70th year he has produced an extraordinary number of pictures. He painted the Emperor William in the last year of that monarch's life; he also executed several portraits of Bismarck, and Von Moltke, whose features have become familiar to the world largely from the numerous reproductions of these imitable pictures, now looked upon as classic examples of German art. Bismarck especially appears in these canvases in every attitude and costume, civil and military which he assumed. Many of these portraits are in the picture galleries of Berlin. But he painted in his time every living man of eminence in Europe from Gladstone to Leo XIII. He also executed many pastel portraits as well as single ideal figures ('Sakuntala,' 'Herodias,' etc.). He was a Royal Bavarian professor. A collection of heliogravure reproductions of his paintings was published at Munich in 1891.

Lenclos, lēn-klō, Anne, French courtesan, better known as Ninon de Lenclos; b. Paris 15 May 1615; d. there 17 Oct. 1705. She was famed for her beauty and notwithstanding her reputation, some of the most respectable ladies of the time cultivated her friendship, and in her old age her house was the rendezvous of the most distinguished personages of the city and court. Scarron consulted her on his romances, St. Evremond on his poems, Molière on his comedies, Fontenelle on his dialogues, and La Rochefoucauld on his maxims. Richelieu is said to have been her first lover, and Coligny, Condé, Sévigné, etc., were her lovers and friends. She retained the charms of her manners and conversation, and to some extent of her person, to extreme old age.

Lend a Hand Clubs, organizations of young persons established in the United States in 1871, for religious, philanthropical and social purposes. The name is derived from a story by Edward Everett Hale, entitled 'Ten Times One

is Ten,' published in 1870. Each club creates its own constitution but follows a common motto:

Look up and not down,
Look forward and not back,
Look out and not in,
Lend a hand.

The badge of the club is a Maltese cross, with the inscription 'In His Name.'

Lenepveu, lä-nā-vé, Charles Ferdinand, French composer: b. Rouen 1840. A pupil of Savard, Ambroise Thomas, and Chauvet, he obtained the Prix de Rome in 1865, and was appointed professor of harmony at the Conservatory in 1881 and of composition in 1893. His works include the sacred drama 'Jeanne d'Arc,' first given in the cathedral of Rouen in 1886, several operas, a requiem mass, 'Méditation' for orchestra, and various choral and solo compositions.

Lenepveu, Jules Eugène, zhü'l é-zhān, French painter: b. Angers 1819; d. 1898. He was a pupil of Picot and the Beaux-Arts, won the Prix de Rome in 1847, painted several canvases ('Les Martyrs aux Catacombes'; 'Venetian Night'; 'Hylas'; and others), and executed many frescoes in public buildings at Paris, Angers, and elsewhere.

L'Enfant, lōñ-fāñ, Pierre Charles, French-American engineer: b. France 1755; d. Prince George's County, Md., 4 June 1825. A lieutenant in the provisional service of France, in whose best military institutions he had been trained, he came to America with Lafayette in April 1777; built Fort Mifflin (on the Delaware), which successfully resisted one of the most vigorous attacks of the Revolutionary War; and by his skill as a designer of fortifications attracted the attention of Washington, who made him chief of engineers, with brevet of major of engineers. He remodeled and refitted the City-hall in New York for the use of the first Congress, and later also the Federal House in Philadelphia. Washington and Jefferson selected him to draw the plan for the "new federal town"; and during the spring and summer of 1791 he was employed in the elaboration of his plans. Jefferson wished the design to be that of a chess-board regularity of squares; but L'Enfant broke the monotony of this arrangement by inserting numerous avenues running at acute angles. His plan was approved by Washington, and he was retained to direct the execution of it. The commissioners in general charge of the work advertised a sale of lots for October 1791, and requested L'Enfant to furnish his plan to be engraved and published. This he refused to do, asserting that speculators would purchase the best locations in the "vistas and architectural squares," and "permanently disfigure the city" by "huddles of shanties." For this insubordination Washington ordered his dismissal 1 March 1792. For planning the "federal city" and devoting his time for months to the survey and other preliminary operations, L'Enfant received only \$2,500 and a lot near the executive mansion, a compensation quite in accord with the general economy with which the work was prosecuted. He requested the commissioners to recall the order for the money and "not take any further trouble about the lot." Later, Madison appointed him professor of engineering at West Point, but he declined the post. He designed several public works at Philadelphia, and was appointed to construct the

LENNO LENAPES — LENS

present Ft. Washington (on the Potomac). He partly executed the work, but disagreed with his superiors, and was dismissed. He lived latterly at Chellum Castle, the residence of Dudley Digges, near Bladensburg, Md., and frequented the halls of Congress, seeking in vain for a reward for past services. The execution of his plan for Washington was continued by his assistant, Andrew Endicott, later professor of mathematics at West Point. L'Enfant's design may be viewed in the Library of Congress. To L'Enfant is chiefly due the fact that to-day Washington is one of the most picturesque cities of the world. See WASHINGTON.

Lenno Lenapes, lén'nó lén'a-péz, the native name for the Delaware Indians (q.v.).

Lennox, Charlotte Ramsay, English novelist: b. New York 1720; d. London, England, 4 Jan. 1804. She was the daughter of the lieutenant-governor of New York and was educated in England. She married and being left a widow in narrow circumstances took up literature for support. Her best work is 'Shakespeare Illustrated' (1753-4). She also wrote 'Memoirs of Harriet Stewart' (1751); 'The Female Quixote,' popular in its day (1752); 'Sophia,' a novel (1763); 'The Sisters,' a comedy (1769); etc. She was the friend of Dr. Johnson and Samuel Richardson, from the former of whom she received much literary encouragement.

Lenormant, Charles, shär'l lē-nôr-män, French archæologist and art historian: b. Paris 1 June 1802; d. Athens, Greece, 24 Nov. 1859. He became inspector of fine arts in 1825, professor at the Sorbonne in 1835 and was professor of Egyptian archæology in the Collège de France from 1848 till his death. Among his writings are: 'Thesaurus of Numismatics and Glyptics' (20 vols., 1834-50); 'Introduction to Oriental History' (1838); 'Museum of Egyptian Antiquities' (1835-42); 'Selection of Keramographic Monuments' (4 vols., 1837-61); 'Historical Questions' (2d ed. 1854).

Lenormant, François, frān-swā, French historian and archæologist, son of Charles Lenormant (q.v.): b. Paris 17 Jan. 1837; d. there 10 Dec. 1882. He is one of the foremost of French Assyriologists and from 1874 was professor of archæology at the Bibliothèque. Among his very numerous works are: 'Archæological Researches at Eleusis' (1862); 'Ancient History in the East' (1868-9); 'Letters on Assyriology' (5 vols., 1871-9); 'Akkadian Studies' (3 vols., 1873-9); 'The Primitive Language of Chaldea' (1875); 'Money of Ancient Times' (1879); 'The Beginnings of History according to the Bible' (3 vols., 1880-4); 'Magna Grecia' (1881-3).

Lenox, James, American philanthropist: b. New York 19 Aug. 1800; d. there 17 Feb. 1880. He was educated at Columbia, and in 1839, on the death of his father, a wealthy Scottish merchant of New York, he inherited a fortune of several millions, and 30 acres of land between Fourth and Fifth avenues. After his father's death he retired from business and devoted his time to study, and the collection of fine books, statuary and painting. After some years he became the possessor of the most extensive private collection of books and paintings in the United States. In 1870 he erected a large

and costly building on Fifth Avenue, between 70th and 71st streets, to contain his collection, and this now constitutes the Lenox Library, which he gave to the city on its completion. It is especially notable for its exceptionally large collection of Americana. He founded the Presbyterian Hospital near the library, his gifts to it amounting to \$600,000. He also made important gifts to Princeton College and seminary, and gave liberally to numerous churches and charities connected with the Presbyterian Church.

Lenox, Mass., town in Berkshire County; on the New York, N. H. & H. railroad; about six miles south of Pittsfield and the same distance from the boundary line between New York and Massachusetts. It was settled in 1750 and named in honor of Charles Lenox, Duke of Richmond. The town includes the villages of Lenoxdale and New Lenox. It is noted for its beautiful scenery and healthy climate. Within the town limits are Laurel and Mahkeenac lakes, and spurs of the mountains called the Ledge, Perry Peak, Bald Head, and Mattoon Hill. This locality is largely residential; the industries which contribute to the wealth of Lenox are located mainly in the large cities. Many noted people have been residents of Lenox, among others Nathaniel Hawthorne. Pop. (1900) 2,942.

Lenox College, a coeducational institution, founded at Hopkinton, Iowa, in 1850, and opened in 1859, under the auspices of the Presbyterian Church. It has a preparatory department and classical courses leading to degrees. In 1903 there were connected with the school 15 instructors, and 170 students. The library contains nearly 6,000 volumes.

Lens. A transparent body, generally glass, which refracts the rays of light convergently or divergently. Converging lenses, properly speaking, are called positive (trade designation plus, +), because they bring rays of light to an

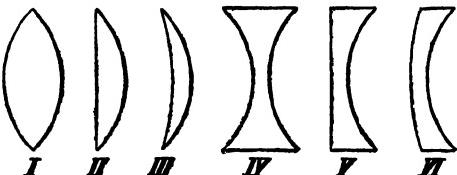

FIG. 1.

actual focus, thus forming a real image. Converging lenses give, under suitable conditions, a magnified image of an object, and one or both of their bounding polished surfaces are convex. The fact of their being thicker in the middle than at the edges distinguishes them from diverging lenses. Diverging lenses are called negative (trade designation, minus, -) because they tend to cause the rays of light to diverge and form, under all conditions, a virtual, reduced image of an object. One or both of their surfaces are concave and they can be distinguished from converging lenses by their being thinner in the middle than at the edges. These two classes of lenses are each divided into three leading types. Those of the positive or convex class are (1) double or bi-convex; (2) plano convex; (3) convex meniscus (trade term, perisopic convex). Those of the negative or

LENS

concave class are: (4) double or bi-concave; (5) plano concave; (6) concave meniscus (trade term, perisopic concave). (See Fig. 1.) Convex lenses converge parallel rays, as shown in Fig. 2, to a point (*c*) called the principal focus

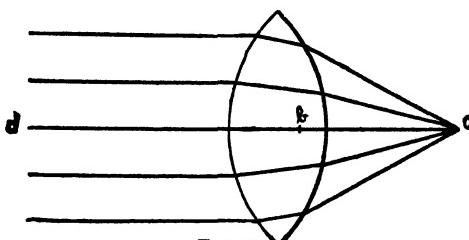

FIG. 2.

or focal point, and the distance from a certain point (*b*), called a principal point, which is usually within the lens, to the focal point (*c*) is the equivalent focal length. The straight line (*d b c*) which passes through the middle of the lens, joining the centres of the curvature of the two surfaces, is called the principal axis.

For brevity, the word "focus" is often used instead of focal length. In a concave lens, the action on parallel rays is opposite to that of a convex lens; instead of converging the light, it diverges the rays away from the axis, as shown in Fig. 3. The imaginary extension of the di-

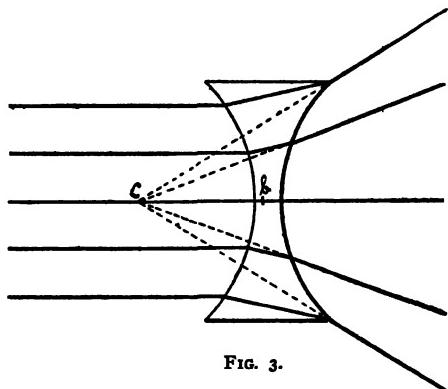

FIG. 3.

verging rays should meet at *c*, and when, as in the case of the convex lens, the incident rays are parallel, the distance from the virtual focus *c* to the principal point *b* is the equivalent focal length. Generally speaking, the real or virtual focus increases with the increase of radius of curvature of the polished surfaces. The power of any lens is the quotient obtained by dividing

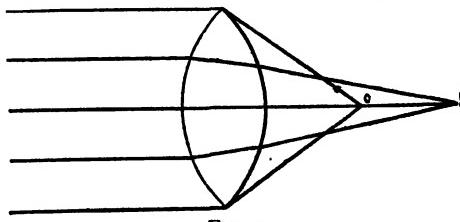

FIG. 4.

unity by the equivalent focal length. A lens is said to be neutralized when combined with one of equal and opposite power, giving the effect

of a plane glass. The distinctness of the image formed by a simple lens depends mostly on the extent to which the spherical aberration and the chromatic aberration are present, the aberrations being greater as the ratio of diameter to focal length increases in a lens of any given type. Spherical aberration of a lens is caused by the rays meeting at different intervals along the axis instead of combining at one point. In Fig. 4, *ol* is the spherical aberration. Chromatic aberration is due to the separation of the light into its different colors, thus causing, in the case of a convex lens, the violet rays to meet at a point *v* nearer the lens than do the red rays at point *r*. In Fig 5, *vr* is the chromatic aberration. Both

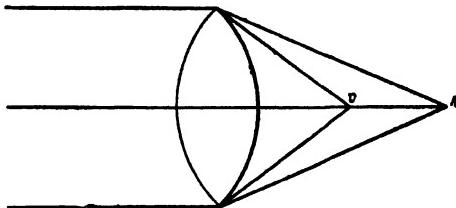

FIG. 5.

of these defects are corrected by means of achromatic lenses.

Up to the present, we have only considered lenses in which the curved surfaces are spherical, and for this reason are called spherical lenses. There are, however, other forms of lenses used, especially for the correction of defects in vision, principally astigmatism, of which the most important has one, sometimes both, of the curved surfaces cylindrical. These are called cylindrical lenses, or cylinders. In these lenses a line drawn along the summit of curvature, parallel to the axis of the imaginary cylinder is called the axis, and must be distinguished from the principal axis of a spherical lens. (Fig. 6.) When the

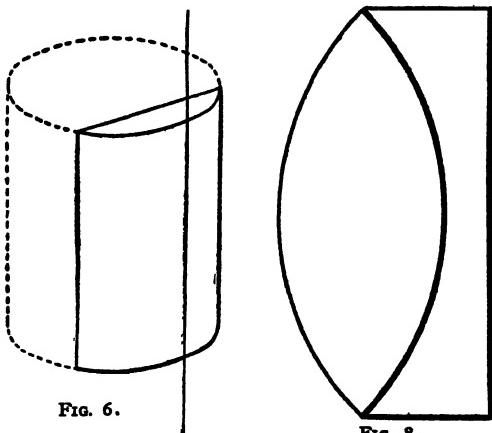

FIG. 6.

lens has two cylindrical surfaces, with the axes at right angles, it is called a "crossed cylinder"; if one of the surfaces is spherical and the other cylindrical, the lens is called a "sphero-cylinder." Another form of lens which has come into use in recent years is the toric (toroidal) lens on which one surface is toroidal, the meridians of the surface are at right angles to each other and

LENS

have radii of different curvature. Its form is illustrated by a section of a bicycle tire. (Fig. 7.)

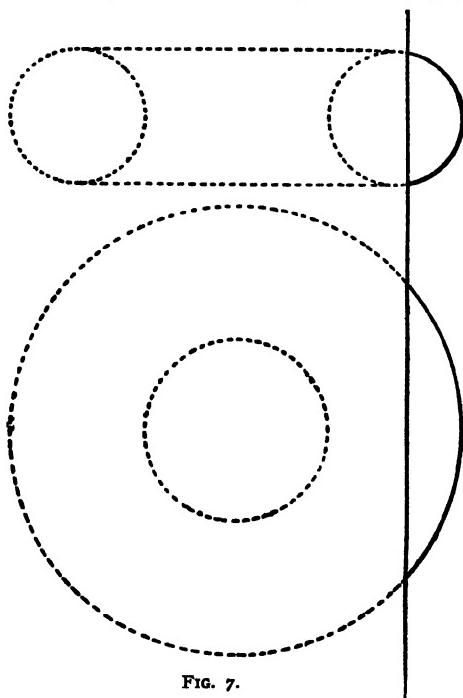

FIG. 7.

History.—The word lens is frequently used to designate a combination of lenses, or of lens-systems, as for example a photographic objective is often called a "photographic lens." The early history of lenses is quite vague. While the magnifying property of glass globes filled with water and presumably of glass beads was known, there is no authentic information that lenses were made and used. There is in the British Museum a piece of rock-crystal about the size of a modern spectacle lens, cut to a plano convex form which was found by Layard during the excavations at Nimroud. Instead of having a spherical surface, it is made up of a series of facets and the crystal is permeated by cloudy striae. Alhazen, who died about 1052, first described the magnifying effect of simple lenses. Spectacle lenses were well known in the 13th century, and their invention is credited to Salvino d'Armatto degli Armati, about 1255. The combination of two single lenses, thus forming a compound microscope, for the purpose of magnifying objects, is believed to be due to Hans and Zacharias Janssen of Middleburg, Holland, about 1590. The discovery of the telescope which is credited to Galileo about the year 1610 was in its original form a combination of a convex lens of long focus with a concave lens of short focus, and this form is still retained in the ordinary opera glass, which is designated as a Galilean telescope. The achromatic lens was the next important invention and was made by Dolland in England in 1758.

Achromatic lens.—In its simplest form is a combination of a converging crown glass lens and a diverging flint glass lens so proportioned that the chromatic aberration is corrected for two colors. These lenses are generally com-

bined by a thin transparent cement which makes them together appear as one lens. (See Fig. 8.) They are also made up of three, four or five lenses.

Aplanatic lens.—A lens or a lens system which is free from spherical aberration.

Apochromatic lens.—An achromatic lens in which the chromatic aberration is corrected for three colors and the spherical aberration is also very perfectly corrected.

Bi-focal lens.—A double focus spectacle lens first introduced by Benjamin Franklin, and now commonly made by adding to or inserting a segment in the lower half of the lens.

Bull's-eye lens.—A plano convex lens of relatively short focus used for illuminating purposes.

Cataract lens.—A short focus convex lens to aid vision after the removal of the crystalline of the eye for cataract.

Coddington lens.—Originally the central portion of a glass sphere but is now generally made a single lens of considerable thickness with convex surfaces, with a circular groove to cut out the marginal rays.

Collective lens.—In a microscope or telescope eyepiece the large lens nearest the objective.

Compound lens (A trade term).—A lens in which combinations of plano, spherical, cylindrical or toric surfaces are made, sometimes to the extent of obtaining a prismatic effect.

Condensing lens.—A convex lens or a system of lenses for concentrating light to a point or on a surface.

Coquille lens (Trade term).—A piece of colored glass of uniform thickness and having concentric spherical surfaces.

Crossed lens.—Either a double convex or double concave lens with the radii of curvature in the proportion of 1 to 6, and giving the minimum amount of spherical aberration.

Crystalline lens.—The double convex lens in the eye situated behind the iris and aiding to form the image on the retina.

Demonstration lenses.—A series of lenses of pronounced curvatures to illustrate the various types of lenses.

Doublet lens.—A combination of two single lenses.

Eye-lens.—The lens nearest the eye in eyepieces (oculars) used for microscopes and telescopes.

Eyeglass lens.—A spectacle lens used to aid vision. As a single lens it is held in position by muscular contraction. The eyeglass with lenses for both eyes is generally accepted to mean the form which is held in position by clamping the nose (French, pince-nez).

Finder lens.—A lens or a combination of lenses attached to a camera to locate an object in the field of view.

Fluid lens.—A lens produced by filling the space formed by two surfaces of transparent media with a suitable media.

Fresnel lens.—A lens formed of a central plano convex or toric convex lens bounded by ring-shaped prisms and lenticular prisms, used to project the rays from a lamp, as in a light-house or signal light.

Immersion lens.—A microscope objective of high power, the front lens of which is connected by fluid to the cover glass of an object, thus giving increased angular aperture.

LENT—LEO

Magnifying lens (Magnifier).—A lens or a combination of lenses used to increase the apparent size of an object, usually mounted in convenient form for the pocket.

Pebble lens (Trade term).—A spectacle lens made of rock crystal which is harder than glass.

Photographic lens (also photographic objective).—A lens or a combination of lenses designed for photographic purposes. It is made in a great variety of types, the simplest being the single achromatic convex meniscus lens. The form in most common use is composed of two separated achromatic menisci, with their concave surfaces toward one another (symmetrical, rectilinear, aplanat). The portrait lens is another type having great light-gathering power, and is composed of two separated achromatic lenses, one cemented and the other uncemented (Petzval type). The most modern photographic lens is the anastigmat, invented by P. Rudolph, which is free from astigmatism, a fault present in all earlier types. The new varieties of optical glass made in Jena were first successfully employed in these lenses, by means of which greater perfection in other directions was also attained.

Spectacle lens.—A lens used to correct vision and when two are combined by a bridge which rests on the nose and provided with bows which clasp the temples is now generally termed spectacle.

EDWARD BAUSCH,

*Of the Bausch & Lomb Optical Co., Rochester,
N. Y.*

Lent (from Anglo-Saxon *Lenc*, spring), the spring or vernal fast of the Christian Church as observed, in preparation for Easter, by members of the Greek, Roman, and Anglican Churches. The original fast of spring which preceded Easter; was of forty hours' duration, this being the number of hours that intervened between the death and resurrection of Christ. Additional days were added, their number varying in different churches. Cassian (420 A.D.) says six or seven weeks was the period in the several churches, but none exceeded 36 fasting days. He affirms that the observance of Lent is not primitive. The historian Sozomen (440 A.D.) writes of the fast "The Quadragesimal fast before Easter some observe six weeks, as the Illyrians and Western Churches; others make it seven weeks, as the Constantinopolitans and neighboring churches." In the first three or four centuries much latitude was allowed in the observance of Lent; Chrysostom recommends, but does not enforce it, insisting on the prior necessity of good works and alms-giving. Distinction of foods was not made in primitive times, when the greatest ascetics ate meat in Lent, though they abstained from eating until the evening. See FASTING, ASH WEDNESDAY, HOLY WEEK.

Len'til, a European leguminous plant (*Ervum lens*), closely allied to the tares and vetches. Lentils are cultivated in southern Europe in two varieties—the large garden lentil and the common field lentil, for the sake of their seeds contained in small pods. The straw of lentils is good food for cattle and sheep, and when mixed with vetches, and sowed as food, are excellent fodder. As food for man they are very nutritious, and in Egypt, Syria, etc., are

a chief article of diet. They are used in soups, etc., in England and America, but not to a great extent.

Lentulus, lén'tü-lüs, the name of a patrician family of Rome of the Cornelian gens. Several of its members distinguished themselves by their virtues and services, while others were less honorably conspicuous. Publius Lentulus Sura, an accomplice of Catiline, was strangled in prison. Lentulus Spinther, one of the most luxurious and ostentatious men of his age, was a partisan of Pompey, but was pardoned by Caesar and joined Brutus and Cassius when they took the field after the assassination of Caesar. To Gneius Lentulus was assigned the command of the legions in Upper Germany during the reign of Tiberius. He was put to death by Caligula.

Leo, lē'ō, the name of six rulers of the Byzantine empire, as follows:

Leo I., called the ELDER: b. Thrace about 400; d. 474. He ascended the throne in 457. After attaining the highest military rank, he was proclaimed emperor by the soldiers in succession to Marcianus. He confirmed the decrees of the Council of Chalcedon against the Eutychians, and renewed the war against the Vandals; but this having resulted in failure the blame was thrown upon his general, Aspar, whom he put to death with his family in 471. The Goths, to revenge the fate of Aspar, poured into the empire, which they laid waste as far as the walls of Constantinople.

Leo II., called the YOUNGER, grandson of Leo I., succeeded his grandfather under the guardianship of his father, who caused himself to be proclaimed emperor a few months afterward. He is said to have been put to death by his own father after reigning from January to November 474.

Leo III., called the ISAURIAN: b. Isauria about 680; d. 18 June 741. Entering the army he became general-in-chief of the army of Asia, under Justinian II. In 716 he marched against Theodosius III., who had been proclaimed emperor on the deposition of Justinian II.; and himself seized the crown the next year. The Saracens, under Solyman, having ravaged Thrace, laid siege to Constantinople, which was defended by Leo, who compelled them to retire. In 726 he ordered all the images in the churches of the empire to be removed, an edict which aroused the memorable contest known as iconoclasm.

Leo IV., grandson of Leo III.: b. 750; d. 780. He succeeded his father, Constantine V., in 775. In his time the controversy raged fiercely between the Iconoclasts, or image-breakers, and their adversaries, both of whom he protected by turns. He repulsed the Saracens in Asia.

Leo V., called the ARMENIAN, from the country of which he was a native, d. 25 Dec. 820. He rose to the rank of general by his valor; but was accused of treason, disgraced, and imprisoned. Michael Rhangabus, on ascending the throne in 811, restored him to his rank; but Leo, profiting by the misfortunes of his master, headed a military revolt and was elected emperor by the troops in 813. He was one of the most violent of the Iconoclastic princes and

LEO

was assassinated before the altar in his palace chapel.

Leo VI., the PHILOSOPHER: b. 865; d. 911. He was the son and successor of Basilius, the Macedonian, and ascended the throne in 886. The Hungarians, Saracens, and Bulgarians having united against the empire, he asked the aid of the Turks, who entered Bulgaria and ravaged it. He drove the patriarch Photius from his seat; and Nicholas, one of the successors of Photius, excommunicated the emperor; for which Leo VI. deposed him. He wrote 'Oracula,' a poem; 'Orationes'; and a celebrated treatise on tactics, printed at Leyden in 1612. Consult: Bury, 'Later Roman Empire' (1887); Oman, 'Byzantine Empire' (1892).

Leo, the name of 13 popes, as follows:

Leo I., Saint, surnamed THE GREAT: b. probably at Rome; d. there 10 Nov. 461. He succeeded Sextus III. in 440 and took decided action against the Manichæans and other heretics. He held a council at Rome against Eutyches in 449, and presided by legates at the General Council of Chalcedon, 451. When Attila invaded Italy, Leo I. who was sent by the Emperor Valentinian to dissuade the invader from his threatened march on Rome, was successful in his mission. He afterward saved the city from being burned by Genseric. His sermons and letters, edited by Ballerini, appeared 1753-7. Consult Arendt, 'Leo der Grosse und seine Zeit' (1835); Gore, 'Leo the Great' (1880).

Leo II., Saint: b. Sicily; d. 683. He succeeded Agatho in 682. He confirmed the decrees of the sixth general council and was instrumental in raising the grade of church music and improving the Gregorian Chant. He was succeeded by Benedict III.

Leo III., Saint: b. Rome; d. there 25 May 816. He succeeded Adrian I. in 795 and his first official act was to acknowledge the suzerainty of Charles the Great (Charlemagne) by sending him the keys of St. Peter's and the standard of the city of Rome. His rule was much disturbed by outbreaks and conspiracies in Rome and in 799 he was obliged to ask the protection of Charles. In the following year, 800, Charles visited Rome, and was there crowned by the Pope, emperor of the Romans.

Leo IV., Saint: b. Rome; d. 7 July 855. He succeeded Sergius II. in 847. The Saracens having invaded the Ecclesiastical States, he marched against them and obtained a complete victory; after which he built the Leonine wall encircling the Vatican quarter, restored the town of Porta, colonizing it with Corsicans, and founded the town of Leopolis, now deserted, some 12 miles from Civita Vecchia.

Leo V.: d. 6 Dec. 903. He was a Benedictine monk who, in 903, succeeded Benedict IV., but was imprisoned by his chaplain Christopher, and died soon after.

Leo VI.: d. 3 Feb. 929. He succeeded John X. 6 July 928, and is said to have been put to death by Marozia.

Leo VII.: d. 939. He succeeded John XI., son of Marozia. He successfully negotiated a peace between Hugo, King of Italy, and Alberic, Duke of Rome, the son of the celebrated Marozia, and is reported to have been an

irreproachable man and zealous ecclesiastic. His successor was Stephen VIII.

Leo VIII.: d. 965. He was intruded in the pontificate on the pretended deposition of John XII., in 963, under the patronage of Otho I., but on Otho's withdrawal John re-entered Rome, and drove away Leo. John's death occurring soon after, Benedict V. was chosen pope. The Emperor Otho subsequently took Rome, and after the banishment of Benedict again intruded Leo, who shortly after died.

Leo IX., Saint (BRUNO): b. Alsace 21 June 1002; d. Rome 19 April 1054. He was cousin to Emperor Conrad the Salic, and became bishop of Toul at 22. At the Diet of Worms, in 1048, he was elected to succeed Damasus II. as Pope. He applied himself to the reform of discipline in the Church, holding several councils against simony and concubinage. In 1058 he opposed the Normans in Italy, but was taken prisoner by their leader, Robert Guiscard, at the battle of Civitella, and confined at Benevento ten months. Falling ill he was allowed to return to Rome. Consult Hunkler, 'Leo der Neunte und seine Zeit' (1851).

Leo X. (GIOVANNI DE' MEDICI, jō-vän'nē dā mā'dē-chē): b. Florence 11 Dec. 1475; d. Rome 1 Dec. 1521. He was the second son of Lorenzo the Magnificent, and his father had him made a cardinal by Innocent VIII. at the age of 13. When the Medici were expelled from Florence, in 1494, he spent some years in travel in Germany, France, and Flanders, and made acquaintance with many eminent men, returning to Rome in 1503 and devoting himself to science and the fine arts. He was appointed by Julius II. legate with the papal army, and in 1512 was taken prisoner by the French at the battle of Ravenna, regaining his liberty only after the evacuation of Milan by the French. In 1513 on the death of Julius II., he was elected Pope, and made his entry into Rome on 11 April, the anniversary of his capture at Ravenna. His pontificate of nine years is one of the most eventful of modern history, when viewed in relation to great political changes, to the revival of literature and, above all, to the Reformation. He succeeded in putting an end to the disputes between Louis XII. and the court of Rome; he continued and brought to a close the Council of the Lateran; and, at a conference held at Bologna, concluded a concordat with Francis I. of France. In 1517 he created the unexampled number of 31 cardinals, among whom were Cajetan, Campeggio, Trivulzio, and other learned and eminent men. He planned a great war against the Turks, and resolved about the same time to complete the church of St. Peter at Rome, and in order to raise funds for these schemes he granted to all the faithful, who should contribute by their alms, certain indulgences, the preaching of which in Saxony was one of the forces which resulted in the Reformation. Leo published his first bull against Luther in June 1520, and Luther appealed to a general council and publicly burned the bull at Wittenberg.

A second bull appeared against Luther in January 1521, and the papal anathema was echoed by the doctors of the Sorbonne. At the same period war was resumed between the Emperor Charles V. and Francis I., the Pope

POPE LEO XIII.

LEO

allying himself first with Francis and soon after with Charles. As an intelligent patron of literature and the fine arts, he was surrounded with many of the most distinguished men of his time. He stimulated the study of Greek and the collection of ancient manuscripts; restored the Roman University and the great Laurentian Library of Florence. Consult: Roscoe, 'Life and Pontificate of Leo X.' (1805); Creighton, 'History of the Papacy During the Period of the Reformation,' Vols. III.-V. (1882-94); Niti, 'Leone X. e la sua politica' (1892); Conforti, 'Leo X. ed il suo secolo' (1896).

Leo XI. (ALLESSANDRO OTTAVIANO DE' MEDICI, äl-lés-sán'drō öt-tä-vē ä'nō dā mā-dē-chē): b. Florence 1535; d. 21 April 1605. He was consecrated Bishop of Pistoria 1573, became Archbishop of Florence in 1574 and entered the college of cardinals. On 1 April 1605 he became pope. He survived only 26 days after his election.

Leo XII. (ANNIBALE DELLA GENGA, än-né-bä'lä dë'l'a jén'ga): b. near Spoleto 1535; d. 10 Feb. 1829. He entered the priesthood in 1783, was made titular archbishop of Tyre ten years later and became a cardinal in 1816. In 1823 he succeeded Pius VII. He was a strong opponent of secret societies, such as the Freemasons and the Carbonari. Consult Artand de Montor, 'Histoire du Pape Leon XII.' (1843).

Leo XIII. The death of Leo XIII., on 20 July 1903, excited the most intense interest throughout the world. The Pope had been ill for many days, and each detail of his sickness had been minutely described and cabled by Roman correspondents to all parts of the civilized world. This, in ordinary cases, might have lessened a sympathy, which, as time went on and the august patient lingered, had become almost strained; but in his, it did not. Irrespective of creed, men's reverence followed the Pontiff to the very tomb, and no discordant voice was heard to break the chorus of esteem for one whose moral force had made sectarian bitterness ashamed of itself.

The death of Leo XIII., philosopher, poet, statesman and priest, has shown that theological hatreds are on the decline.

In Carpineto, on 2 March 1810, Joachim Vincent Raphael Lodovico Pecci was born. His father was Count Domenico Lodovico Pecci, then—1810—in his forty-first year and his mother Anna Prosperi-Buzi, then in her thirty-seventh. The palace in which Joachim was born was the country house of the family, high in the mountains.—a nest for an eagle. Count Lodovico Pecci confided his sons, Joseph and Joachim (or Vincent) to the Jesuits of Viterbo, who very recently had been restored by Pius VII. to the privileges of which Clement XIV. had deprived them. In 1818, Joachim Pecci began his education in the Jesuit college of Viterbo. He was a fragile boy,—this boy who was to become Pope at 68 and whom death found it hard to conquer at 93—and he knew nothing of the happy robustness of other boys, in spite of his frequent vacations in his native hills. That devotion to the Greek and Latin classics which later gave him fame as a poet, showed itself early. At the age of twelve he was skilled in writing Latin

verse. There still exists an epigram for the provincial of the Jesuits,—

Oh, utinam possem Peccius ipse sequi.

In 1824, Leo XII. carried further the plans of Pius VII. and re-opened the Roman College of the Society of Jesus. This college is likewise known as the Gregorian University. Young Pecci entered and applied himself to his studies with so much earnestness that his health gave way, and, in 1830, though he received the highest honor—that of being chosen for a public disputation in philosophy on theses taken from the whole course,—the Prefect of Studies was obliged reluctantly to excuse him. Still he strove for that perfect health which was denied him. He was a mighty hunter and his gun,—very old-fashioned, with a barrel decorated in the Arabian manner,—is still preserved, and he walked great distances.

In 1832, Joachim Pecci took the degree of doctor, with all possible honors, chiefly recorded in the annals of the Sapienza University. In the College of Noble Ecclesiastics he studied Canon and Civil Law. In 1837, Gregory XVI. named him domestic prelate, and he became known as Monsignor Pecci. On the last day of the year 1837, he was ordained priest by Cardinal Odescalchi, the Vicar General of Gregory XVI. One of the most important epochs in the history of Mgr. Pecci is his administration of the Duchy of Benevento. It was the haunt of smugglers and brigands, licensed by public opinion and supported by noble families. It had given Gregory XVI., who was a lover of justice and order, profound anxiety. At the age of twenty-eight Mgr. Pecci was made Delegate and sent to do what the Neapolitan neighbors of Benevento sneeringly said was "impossible." Mgr. de Z'Saeclaes well says that his government of Benevento is "a little epic." He was then called to Spoleto. From thence he went to Perugia, where he busied himself in perfecting measures for the economic and educational progress of the place. The capital of Umbria still reveres him as its benefactor, and his records at Benevento and Perugia,—one destructive of evil, the other constructive of good,—indicated what his future was to be. Early in January 1843, he was chosen for a difficult diplomatic post, the Nunciature at Brussels, and on 19 February he was consecrated Archbishop of Damietta. In Belgium the educational question was burning, and in March 1843, when Archbishop Pecci presented himself to the Court of Brussels, the veteran diplomats smiled at the prospect of a struggle between the Papal Nuncio and that Leopold of Saxe-Coburg, who held the winning cards. The Queen's sympathies were with the Nuncio; she believed in religious education, but the feeling against the "Ultramontanes" ran high; notwithstanding, the Nuncio succeeded in gaining the good-will of all classes and gradually overcoming rancour. This made it all the more astonishing that he should have been recalled from Brussels in 1845. In 1846, he visited London and Paris. He was destined to be Bishop of Perugia; Gregory XVI. died shortly after his arrival in Rome. Pius VIII., the predecessor of Gregory, was followed by another Pius,—Cardinal Mastai Ferretti—who appreciated the value of Pecci so greatly that he felt that as Archbishop of Perugia the late

LEO — LEOCHARES

Nuncio to Brussels could be of more service in healing internal discord than in placating foreign kings and cabinets. He was really, in 1846, only Bishop of Perugia, but as he had been the Titular Archbishop of Damietta, he retained the higher title. He was preconized, — solemnly proclaimed in conclave,— the Bishop of Perugia, on 19 Jan. 1846, and on 26 July he made his solemn entry into the capital of the country of St. Francis d'Assisi. From 1846 to 1878, he ruled in Perugia. He was, in the language of the Psalmist, both a ruler and a shepherd. In the Consistory of 18 Dec. 1853, he was created Cardinal. During his long episcopate, he found the world in miniature in Perugia. The growing antagonism against the church haunted him. He was all for the things of the spirit,— the things of the mind, postulating the truth of the divinity of Christ and the reality of his birth, death and resurrection. In this line, he refutes the claims of Renan, in his 'Life of Jesus,' as eagerly as he refutes false Socialism later, in a Papal Letter.

On 7 Feb. 1878 Pius IX. died. On Monday, 18 February, the Cardinals met in conclave. Pecci, as Cardinal Camerlengo, walked last in the procession. On Wednesday, 20 February, by a vote of forty-five out of sixty-one, Cardinal Pecci became Pope. From 20 Feb. 1878 to 20 July 1903, Leo XIII. was constantly active. He restored the Catholic hierarchy to Scotland, early in 1878, and issued his first Encyclical, *Inscrutabile*, against the forces at work for the disintegration of society — putting strong accent on the disregard of the sacramental character of marriage.

In 1878-9 Leo XIII. was in a most difficult position with the Government of Germany. This later year marks the beginning of the decay of the Kulturkampf which strengthened the Centre party in Germany and which made the name of Bismarck detested by German Catholics at home and abroad. In 1879 came the Encyclical, *Quot Apostolici*, followed by the *Aeterni Patris* — all encyclicals taking their names from the opening words. The first was aimed at that Socialism "which attacks all that has been wisely decreed by human and divine laws for the protection and ornament of life"; the second is an exposition of the claims of St. Thomas Aquinas as a philosopher.

Another important encyclical,— it is not possible to name them all,— appeared on 12 Feb. 1880. It was the *Arcanum*, on Christian marriage. Another, 29 June 1881, was the encyclical *Diuturnum* in favor of rightful authority. "The Church," he said, "was everywhere the friend of honest liberty; she detested tyranny." In 1882 he strove to keep the Irish movement within legal bounds. The encyclical *Etsi Nos*, of February 1882, gave rise to the rumor that he would leave Rome, so "intolerable" had the situation become. In 1890, the world gradually learned that for six years every historical document in the Vatican had been at the service of scholars. He omitted nothing that could add to the progress of historical science. The encyclical, *Humanus Genus*, was aimed at Freemasonry, which assumes an atheistical and anti-religious aspect in Latin countries.

Leo XIII. was aroused to intense enthusiasm for the work of Cardinal Lavigerie in breaking down the slave-trade in Africa, and his encyc-

lical, *In Plurimis*, 5 May 1888, is evidence of his detestation of slavery. It is addressed to the bishops of Brazil. The prudence with which Leo XIII. handled the question of the Knights of Labor was due to the tact he possessed of discovering the best advisers. There were forces at work urging the condemnation of this society; but, owing to the sanity and energy of Cardinal Gibbons, Cardinal Manning and Mgr. O'Connell, now rector of the Catholic University (1903), a disaster by which suspicion and dislike to the Church might have been excited was avoided.

The relations between the late Pope and the United States of America were very close. He appreciated the messages of President Cleveland; and he frequently expressed himself touched by the respect with which President Roosevelt, representing the American people, treated him. He established the Catholic University at Washington, and constantly expressed interest in it. Leo's interest in the Columbian Exposition at Chicago surprised Europe. His solicitude for the Church in America was profoundly shown in the Apostolical letter, *Testem Benevolentia*, on "Americanism," in which he paternally determines and settles a point for some time in controversy among American Catholics. In the beginning of the year 1893, Mgr. Satolli, afterward Cardinal, became the first Apostolic Delegate to the United States. This is not a diplomatic but a purely ecclesiastical office. Cardinal Satolli was succeeded by Mgr., now Cardinal, Martinelli, and (1903) by Mgr. Falconio, late delegate to Canada.

The efforts of Leo XIII. to direct attention to the study of the Scriptures are historic. Perhaps of all his letters which have a diplomatic character, that written to the French in 1892 caused the greatest discussion. It was received by French Royalists with ill-concealed disgust. There is no question that the pontificate of Leo XIII. was of vital value in the history of the last quarter of a century.

As a poet, Leo XIII. wrote exquisite Latin verse, a translation of which has been made by the Jesuit fathers at Woodstock, Md., and a later and fuller one by Dr. Hugh Henry, of Overbrook Seminary, in Pennsylvania.

MAURICE FRANCIS EGAN,
Professor of Literature, Catholic University of America.

Leo ("the lion"), in astronomy, the name given to one of 12 zodiacal constellations. It contains about 100 stars visible to the naked eye, the chief star being Regulus. The sun enters the sign Leo about 21 July. Leo Minor, the Lesser Lion, is a constellation found by Hevelius about 1691. None of its stars reach the fourth magnitude. Leonides are meteors radiating from the vicinity of Leo, usually seen about 14 November.

Leo Minor. See LEO.

Leochares, lē-ōk'a-rēz, Greek sculptor of the 4th century B.C. He was a pupil of Scopas, and Pliny ascribes to him the sculptures on the west side of the Mausoleum at Halicarnassus. He was one of the artists privileged to make portraits of Alexander the Great. Three statues of Zeus are known to have been executed by him, and his 'Ganymede carried off by an Eagle' was famed throughout the ancient

LEOMINSTER—LEONARD

world. With Lysippus he produced a colossal bronze group representing Alexander at a lion-hunt. The works of Leochares are all lost, but there is a copy of the Ganymede in the Vatican; and a bust of Alexander may be a copy of one of his.

Leominster, lēm'īn-stēr, Mass., a town of Worcester County, 40 miles west-northwest of Boston, on the Nashua River, and on the New York, N. H. & H., and the Boston & M. R.R.'s. The town is well laid out, has handsome residential sections, six churches, twenty schools, a public library of over 18,000 volumes, and a fine park. Leominster is well lighted with gas and electricity and has a good water supply and abundance of water power, the waterworks being municipalized. It is a busy industrial centre, the home of the comb-manufacture of the State, of piano cases and pianofortes, has large cabinet works, paper mills, tanneries, and extensive manufactures of cement, bricks, yarn, jewelry, toys, buttons, and hairpins. The town is surrounded by some of the most fertile farm land in the county, and horticulture and floriculture are growing industries. Leominster, settled in 1725, was part of Lancaster until 1740 when it received a charter of incorporation. Pop. (1900) 12,392.

Leon, lā-ōn', **Antonio**, Mexican soldier: b. 1794; d. 1847. Having abandoned the side of the royalists for that of the insurgents under Iturbide, he distinguished himself in 1821 by the capture of Tehuantepec, for which he was made lieutenant-colonel. When, however, Iturbide proclaimed himself emperor, the support of Leon was given to Gen. Bravo, the republican leader. In 1824, as deputy from Oaxaca, he served in the Constituent Congress, and later he aided in quelling insurrection against the authority of the republic. He was killed at the battle of Molina del Rey in the war with the United States.

Le'on, Iowa, town, county-seat of Decatur County; on the Chicago, B. & Q. and the Keokuk & W. R.R.'s; about 68 miles south of Des Moines, and nearly midway between the Mississippi and the Missouri rivers. It is situated in a fertile agricultural region, and its industries are connected chiefly with farm products and live-stock. It is the trade centre for nearly all of Decatur County. Pop. (1900) 1,905.

Leon, lā-ōn', city in Nicaragua, on a large and fertile plain 13 miles from the Pacific coast. It is laid out on a regular plan, in spacious streets, with intervening squares. The public buildings are considered among the finest in Central America, and include a large and massive cathedral, crowned by a lofty central dome, and flanked by two towers. Other buildings are the old Episcopal palace (built 1678), surrounded by fine gardens; the new Episcopal palace (1873), the churches of La Merced, Recolección, and Calvario, remarkable for their size and fine façades, and various other churches; the Tridentine College of St. Ramon, once a flourishing establishment, with professorships of law and medicine, and numerous students, but now possessed only of a nominal existence; the government-house, Cuartel General or head barracks, and the hospital, occupying the old convent of San Juan de Dios.

The manufactures of Leon are confined chiefly to articles in dressed leather and cutlery; and the trade, owing to its inland situation, does little more than supply its local wants, but the railway between Leon and Corinto on the coast has somewhat improved it. The markets display fruits and vegetables in great variety and almost boundless profusion. Pop. (1900) 32,000.

León, Philippines, a pueblo of Iloilo, Luzon, situated in the southwestern part of the province near a river, 15 miles northwest of the provincial capital, Iloilo. Pop. 14,000.

Leon, Spain, (1) an ancient northwest province and former kingdom, united to Castile in the 11th century, and now divided into the provinces of Leon, Zamora, and Salamanca; (2) a modern province in the north, with an area of 5,936 square miles and a population (1900) 380,083; (3) a city, the capital of the province, on the Bernesga, 176 miles northwest of Madrid. It is of mediæval appearance, surrounded by dilapidated walls, and has a beautiful park and some fine ecclesiastical structures, including a perfect Gothic cathedral. Pop. (1900) 17,022.

Leon de los Aldamas, dā lōs āl-dā'mās, Mexico, city in the state of Guanajuato, 32 miles west of the capital of the district. The town is well built and prosperous and is in the centre of a rich agricultural district. It has a public square, cathedral, convents and schools, and has numerous industries including cotton and woolen mills. The town was founded in 1576. Pop. (1900) 48,000.

Leon, Ponce de. See **PONCE DE LEON**.

Leonard, lēn'ērd, **Abiel**, American Protestant Episcopal bishop: b. Fayette, Mo., 26 June 1848; d. Salt Lake 23 Dec. 1903. He was graduated at Dartmouth College in 1870, and at the General Theological Seminary, New York city, in 1873. Entering the ministry of the Protestant Episcopal Church, he served in Missouri and Kansas until 1888, when he was consecrated bishop of Salt Lake.

Leonard, Daniel, American jurist: b. Norton, Mass., 29 May 1740; d. London, England, 27 June 1829. He was graduated from Harvard in 1760 and after studying law became a Whig member of the General Court. Disapproving of the extreme measures of the Whigs, his sympathies were with the Loyalists and his papers signed 'Massachusetts' and published in a Boston newspaper in 1774-5, were replied to by John Adams over the signature 'Novanglus.' Leonard's articles ably defended the position of the English government and they constituted the strongest statement of that position put forth in the colonies. In 1776 he went with the English army to Halifax, N. S., and was among those named in the banishment act of 1778, while his property was confiscated by the act of 1779. He went to England from Halifax and was subsequently for many years chief justice of the supreme court of Bermuda. In 1819 John Adams published the 'Novanglus and Massachusetts' with a preface. Consult Tyler, 'Literary History of the American Revolution.'

Leonard, James Francis, American telegrapher: b. Kentucky 1804; d. 1862. He was

LEONARD — LEOPARD-CAT

practically the earliest telegrapher to read messages by sound and for his time was the swiftest telegraph operator in the world. In the summer of 1848 he began to receive messages by sound and soon afterward received and wrote out 55 words a minute for Professor Morse, as a test of the invention. He is buried in Frankfort, Ky., where his grave is marked by a monument erected by telegraphers.

Leonard, William Andrew, American Protestant Episcopal bishop: b. Southport, Conn., 15 July 1848. He was educated at Phillips Academy, Andover, Mass., and St. Stephen's College, Annandale, N. Y., and was graduated at the Berkeley Divinity School, Middletown, Conn. In 1873 he was ordained a priest; became assistant at Holy Trinity Church, Brooklyn, N. Y., rector of the Church of the Redeemer there, then rector of Saint John's Church, Washington, D. C., and was chaplain of the 23d regiment of the National Guard of New York and of the Ohio Society in that city. He is now (1904) bishop of Ohio, having been consecrated 12 Oct. 1889. His writings include 'Via Sacra, or Footprints of Christ'; 'History of the Christian Church'; 'New York Church Club Lectures'; 'A Faithful Life'; 'Witness of the American Church to Christianity' (Bedell Lectures, 1894); etc.

Leonardo da Vinci, lā-ō-när'dō dā vēn'chē. See VINCI.

Leoncavallo, Ruggiero, rūd-jā'rō lā-ōn-kä-väl'lō, Italian composer: b. Naples, Italy, 8 March 1858. He was educated at the Naples Conservatory of Music and for many years resided as a teacher in Paris, where he composed songs and fugitive pieces. Under the influence and encouragement of Wagner he wrote his trilogy 'Crepusculum,' a drama of Italian history, of which 'Medici' is the first part. He is best known by his operas 'I Pagliacci' (1892); and 'La Bohème' (1897). Other works by him are 'Tomaso Chatterton' (1896), a popular opera; and 'Serafitus-Serafita,' a symphonic poem.

Leonidas (lē-ōn'ī-dās) I., king of Sparta: d. 420 B.C. He was a son of King Anaxandrides, and ascended the throne 491 B.C. When Xerxes invaded Greece, the Greek Congress assigned to Leonidas the defense of the pass of Thermopylae. His force, according to Herodotus, amounted to over 5,000 men, of whom 300 were Spartans. After the Persians had made several vain attempts to force the pass, a Greek named Ephialtes betrayed to them a mountain path, by which Hydarnes led a body of Persians to attack Leonidas in the rear. Before this maneuver could be completed, Leonidas, dismissing all his allies except the Thespians and Thebans, advanced from the pass and threw himself upon the main body of Xerxes' army. He fell early in the action, and a desperate struggle afterward took place over his body, which was rescued by the Greeks.

Leonides, or Leonids. See LEO.

Le'one'ne Verses, a kind of Latin verse, in vogue during the Middle Ages, consisting of hexameters and pentameters of which the final and middle syllables rhyme. They are so called from Leonius, a poet of the 12th century.

Leon'todon. See HAWKBIT.

Leopard, lēp'ard, or **Panther**, one of the great cats widely distributed over Africa and Asia, and prehistorically prevalent in southern Europe. The general color is yellowish fawn, which becomes white on the under aspect of the body, marked with black spots of various sizes, irregularly dispersed; these spots are often rosette-like, but do not enclose a central spot as is the case with its American analogue, the jaguar (q.v.). Black examples often occur. In general appearance and conformation the leopard is tiger-like, but is considerably the inferior of the tiger in size and weight, measuring on the average about three feet and ten inches from the nose to the root of the tail, which is almost as long as the body. This beautiful cat is, however, the peer of the tiger, making up in agility, quickness and wit for its defects in weight and power. Its prey consists of any animal it is able to pounce upon or overcome, and among the native villages and herdsman of both India and Africa it is dreaded as a destroyer of cattle and sheep, since, like the American puma, when it invades a cattle-pen or sheep-fold it kills many times more animals that it can eat or carry away,—a hundred sheep in a night. Nevertheless, leopards have always been among the partly tamed and trained animals of shows, and they thrive well and breed in captivity.

The leopard—which is more commonly called "panther" in India—frequents mainly wooded and rocky regions, where it can take refuge in trees, or seek among their limbs the birds, monkeys and other arboreal creatures that form a fair share of its food. It does not hesitate to attack large prey, but can rarely overcome a buffalo or one of the larger African antelopes unless the animal is taken at a great disadvantage. Not more than one pair is usually found in a given district; and they make their lair in some rocky jungle, where once a year two to four kittens are born to them, which remain with their mother until they are well grown. One hears less of man-eating leopards than of lions and tigers with the habit of attacking human beings; but the leopard is more widespread, numerous and subtle than either of the others and doubtless is the real perpetrator of many homicides attributed to the larger cats. At any rate the leopard is regarded by those familiar with him as quite as formidable a beast to encounter, and sportsmen adopt the same methods and use the same precautions as when they are pursuing the tiger. A most excellent summary of leopard-hunting experiences may be read in Porter's 'Wild Beasts' (New York, 1894). For the leopard in India consult Sanderson, 'Thirteen Years among Wild Beasts in India' (1893); Forsyth, 'Highlands of Central India' (1889); Hornaday, 'Two Years in the Jungle,' and similar writers. The Persian leopard is described at length in Blanford's 'Zoology of Persia' (1876); and the African by Baker, 'Wild Beasts and their Ways' (1890); Drummond, 'Large Game and Natural History of Southeast Africa' (1875); and many other sportsmen-travelers in that continent. See CHEETA; SNOW-LEOPARD.

Leopard-cat, a highly variable, tawny, much-spotted cat about two feet long in body, and with a long tail, which dwells in northern

LEOPARDS.

1. The Leopard or Panther. 2. Snow Leopard or Ounce. 3. Hunting Leopard or Cheetah.

LEOPARD-FLOWER — LEOPOLD

India but is not well known. It is called *Felis bengalensis* by Elliot and also by Mivart, but its identity is doubtful.

Leopard-flower. See BLACKBERRY LILY.

Leopard-frog. See FROG.

Leopard-moth, a large European tussock-moth (*Zeusera pyrina*), white spotted with black, whose caterpillars bore into the limbs of forest and shade trees, and so weaken them that they die or are easily broken by the wind. This moth has been introduced to America in the neighborhood of New York where it is one of the pests in the parks.

Leopard-shark, a handsomely variegated small shark (*Triakis semifasciatum*), often seen along the coast of southern California.

Leopardi, Giacomo, já'kō-mô lá-ô-pär'dé, COUNT, Italian scholar and poet: b. Recanati, in the marshes of Ancona, 29 June 1798; d. Naples 14 June 1837. He devoted himself from an early age to study in the fine library of his father, and when he reached his 15th year was master of Latin and Greek, and had soon read most of the literary masterpieces of antiquity. In 1815 his translation of Porphyry's 'Life of Plotinus' was followed by his 'Saggio sopra gli Errori degli Antichi.' He was of profound poetic genius and mourned over the degraded political condition of his native land, a feeling which found utterance in his magnificent 'Ode to Italy' a poem which proclaimed him the first of modern Italian singers. In 1822 he went to Rome and attracted the attention of Niebuhr by his criticism of a new edition of the 'Chronicon of Eusebius'; and the great historian attempted in vain to settle him as professor in the University of Berlin. Leopardi was broken in health, as well as in spirit, and his unhappiness was intensified by an unhappy love affair. Bunsen offered him such a professorship and it was declined. He left Rome to travel in Italy, his tour embracing many of the great northern cities, and ending with Naples. He developed the most absolute skepticism, and the unhappiness of his lot made him a pessimist. His sight failed and he was forbidden to take up a book, and though he was a linguist of rare accomplishments, wrote in Greek and Latin with equal ease, had mastered French, Spanish, and English, he could apply his attainments to no practical end. His classic training had, however, given him a power and precision in the use of his native tongue, which was unprecedented in his day. His early lyrics were written between 1816 and 1824, and are distinguished for lucidity, genuine feeling and brilliant command of metre and rhyme. His most famous poem, however, is 'La Ginestra' (1836), in which he gives full expression to his hopeless creed, and his poetic productions, some 39 remain to this day the finest and most imperishable utterances of the Italian lyre. His other works include translations, and critical treatises, and after his death were published his prose works, a miscellany of peculiar interest. His 'Epistolario,' a collection of his letters, illustrates his personal life. Consult: Autard, 'Essay sur les Idées philosophiques et l'Inspiration poétique de Giacomo Leopardi' (1877); Ranieri, 'Sette Anni di Sodalizio con Giacomo Leopardi' (1880); Cappalletti, 'Bibliographia Leopar-

diana' (1882); Cesareo, 'Nuove Ricerche su Giacomo Leopardi' (1893).

Leopold (lé'ô-pöld) I. (GEORGE CHRISTIAN FREDERICK), king of the Belgians: b. Coburg 16 Dec. 1790; d. Laeken 10 Dec. 1865. He was the son of Francis, duke of Saxe-Coburg, and after receiving careful literary and scientific education became a general in the Russian army and was present at the battles of Lützen, Bautzen, and Leipzig. While in England after the peace of 1815 he married Princess Charlotte, heiress of the throne, and was naturalized by act of Parliament in 1816. The princess died in 1817; and Leopold 12 years later married morganatically Caroline Bauer. In February 1830, he was offered the crown of Greece, but declined it. In June 1831, he was elected by a national congress king of the Belgians, and was crowned at Brussels in the following July. He ruled with great prudence, having continual regard to the principles of the Belgian constitution. His daughter, Carlotta, was the wife of Maximilian, emperor of Mexico. Consult Juste, 'Les Fondateurs de la Monarchie belge, Leopold Ier Roi des Belges' (1868) an English translation of which appeared, entitled 'Mémoires of Leopold I.' (1868); Taillandier, 'Le roi Leopold et la reine Victoria' (1878).

Leopold II., LOUIS PHILIPPE MARIE VICTOR, king of the Belgians: b. Brussels 9 April 1835. He is a son of Leopold I. and was married in 1853 to Marie Henriette, Archduchess of Austria (b. 1836; d. 19 Sept. 1902), daughter of Archduke Joseph of Austria. He early manifested an interest in Africa and in 1876 organized at Brussels the African International Association, the aim of which was to utilize African discoveries. He assisted Stanley in the latter's explorations of the Congo. The Berlin Conference of 1885 established the Congo Free State and conferred its sovereignty upon King Leopold.

Leopold I., emperor of Germany: b. Vienna 9 June 1640; d. there 5 May 1705. He was the 4th son of the emperor Ferdinand III. of the house of Hapsburg, and of Maria Anna of Spain, and was educated for the church, when the death of his brothers made him heir to the throne of his father. Previous to the death of the latter in 1657, Leopold had been crowned king of Hungary; still mainly in Turkish hands. The war with the Turks having been renewed in 1660, Montecuculi won the battle of St. Gotthard on the Raab (1 Aug. 1664), which was followed, however, by a peace which the Hungarian partisans of the emperor regarded as ignominious. In 1678 occurred the great insurrection under Tökolyi, and in 1683 the Turkish invasion of Austria under Kara Mustapha. Leopold fled from Vienna, but John Sobieski's great victory saved his capital and thrones. Buda was retaken after a memorable siege in 1686, and the victories at Zalánkemén (1691) and Zenta (1697) led to the peace of Carlovitz (1699), which also secured the possession of Transylvania. But neither the wholesale executions of Hungarian patriots at Eperies, nor the acquiescence of the diet of Presburg in the proposition to make the male line of the Hapsburgs hereditary in Hungary (1687), could make peace permanent in that long distracted country; and Leopold, who also had to wage

LEOPOLD — LEPIDOPTERA

three protracted wars against Louis XIV. In the German empire the long reign of Leopold witnessed the growing power of the house of Brandenburg under Frederick William, the great elector, whose son assumed the royal title under the name of Frederick I. in 1701.

Leopold II., emperor of Germany: b. Vienna 5 May 1747; d. there 1 March 1792. He was the 3d son of the emperor Francis I., and succeeded him in 1765 on the throne of Tuscany. The death of his brother Joseph II. in 1790 called him to the greater cares of the vast Austrian dominions and soon after of the German empire. He hastened to make terms with Frederick William II. at Reichenbach (27 July 1790), was unanimously elected German emperor, pacified Hungary by taking the royal oath to observe strictly the constitution and by various concessions, proclaimed a full amnesty and restored all their ancient privileges to the Belgians, gave Tuscany to his son Ferdinand, concluded a peace with Turkey at Sistova (4 Aug. 1791), concerted with Frederick William, Frederick Augustus of Saxony, and others, at Rilnitz, preliminary measures for meeting the aggressions of the French revolution, and finally made a formal defensive and offensive alliance with Prussia (February 1792). Of his 16 children his eldest son Francis succeeded him on the throne.

Lepanto, Battle of, a famous naval engagement fought near the town of Lepanto in Greece, on the Gulf of Corinth, 7 Oct. 1571, between the Ottoman and the combined Mediterranean fleets of the Christian allies, who under the command of Don John of Austria obtained an overwhelming victory. Cervantes (q.v.), the author of 'Don Quixote,' distinguished himself in this battle, receiving three wounds.

Lepanto-Bontoc, lä-pän'tō-bōn-tōk', Philippines, a province of Luzon formed by the union of the three sub-provinces of Lepanto, Bontoc, and Amburayan, occupying the western central part of northern Luzon; area 1,232 square miles. The province mostly is rugged and mountainous; it is thinly settled and there are no roads, communication being by trails. The only industry of importance is copper mining. Civil government was established in May 1902. Pop. 60,000, mostly Igorotes and Ifugao.

Leper. See LEPROSY.

Lepid'olite, or Lithia Mica, an important member of the mica group of minerals, as it is now one of the chief sources of the lithia salts so valuable in medicine. Its name, derived from the Greek, lepis, a scale, alludes to its usual occurrence in fine, scaly-granular masses. It rarely occurs in distinct, monoclinic crystals. It has a pearly lustre and a gray, lilac, or peach-blossom pink color. It occurs in small quantities in many parts of Europe and Asia, but by far the most important locality is in San Diego County, California, where it is now extensively mined. It is also found in Maine and Massachusetts and has been mined near Haddam, Connecticut. It is very frequently associated with pink and green gem tourmalines.

Lepidoptera (Gr. λεπίς, scale; ἥπα, wing): An order of the class *Insecta*, comprising the butterflies and moths. The name was given to the order because the wings are covered with little scales, or flattened hairs. The *Lepidoptera* undergo in their development a complete

metamorphosis, passing through the stages of the egg, larva, and pupa, before appearing as the perfect insect, or imago.

Eggs.—The eggs of the *Lepidoptera* are minute objects, though generally large enough to be seen with the naked eye. When examined under the microscope they are found to vary greatly in form according to the species. They may be spherical, hemispherical, oval, conic, cylindrical, spindle-shaped, or flattened. The eggs of the *Cochlididae*, or slug-moths, are circular, or elliptical, and greatly flattened, resembling microscopic pancakes. The egg of the common cabbage-butterfly is spindle-shaped. The eggs of both butterflies and moths are generally beautifully fluted with raised lines, or ornamented with a net-work of sculpturings arranged in geometrical patterns. They are always provided with a minute opening in the shell known as the micropyle, permitting them to be fertilized. This is located at the apex in most forms, but in the case of those eggs which are flattened the micropyle is located on the side. The female deposits the eggs upon the plant on which the caterpillars feed, or in close proximity to the food which is to nourish them, in the case of those few species which do not subsist in the larval stage upon vegetable matter.

Larvæ.—When the eggs hatch the insects appear as larvæ, or caterpillars. These undergo successive molts as they increase in size, shedding their skins from time to time until they have attained the development at which the next transformation, known as pupation, occurs. The bodies of larvæ consist normally of thirteen segments, or somites, of which the first is the head. The forms of the larvæ are very various, though in the main they are vermiform and cylindrical. The larvæ of butterflies are for the most part smooth, though in some genera they are curiously ornamented with lateral or dorsal projections, which may be spinous, club-shaped, or filamentous. The larvæ of moths are often hairy, or spinose, and in some genera of the *Lasiocampidae*, the *Cochlididae*, and the *Saturnidae*, these spines possess stinging, or poisonous properties. Lepidopterous larvæ possess three pairs of true feet located upon the three segments immediately following the head, and corresponding to the six thoracic feet which are found in the winged form of the insects. In addition to these true feet the bodies of these larvæ are supported by from two to eight pairs of abdominal prolegs, or false feet, which are fleshy and do not recur in the imago. The head is always more or less conspicuous in the larval stage, and is provided with eyes and mouth parts adapted to cutting and deglutition.

One of the most remarkable portions of the anatomy of lepidopterous larvæ are the two long glands located in the dorsal region, which secrete a milky fluid, which is vented through a nipple-shaped organ upon the lower lip known as the spinneret, and which upon exposure to the atmosphere is transformed into the substance known as silk.

Pupæ.—When the larva has attained maturity it is transformed into a pupa. Pupæ may be naked, or they may be enclosed in a structure of silk known as a cocoon. The pupæ of butterflies are usually attached by their anal extremities to twigs, the under side of rails, or stones. The attachment is effected by means of a button of silk into which the hook-like cremaster is

LEPIDOSIREN

thrust. In some families chrysalids are in addition held in place by a girdle of silk. The larvæ of moths usually undergo pupation in a cocoon which may be densely woven or very loosely constructed of a few strands of silk mingled with hairs from the body of the caterpillar, or loose particles of adherent earth or fragments of leaves. Many of the hawk-moths and almost all of the owl-moths undergo transformation in underground cells which the caterpillars mold for themselves in the soil before changing into pupæ. The duration of the pupal stage varies in length according to the species, or the season. Many species in temperate climates pass the winter in the pupal form. Where there are two or more generations in a season the pupal period is short for the summer broods, and the fall brood hibernates in the pupal state. The pupæ of butterflies are often ornamented with silvery or golden spots, hence the name *chrysalis* has been applied to them, the word being derived from the Greek (*χρυσός*, gold). The pupæ of moths are generally some shade of brown or black. The pupa contains the imago and in almost all cases an examination will show in the pupa the location of the various organs of the perfect insect in a rudimentary form.

The Imago.—When the period of pupation is ended the butterfly or moth breaks through the pupal shell and emerges a four-winged, six-footed insect, known as the *imago*. The females of some species of moths are apterous, or provided with wings so poorly developed that they cannot be used in flight.

Classification.—The classification of the Lepidoptera has afforded opportunity for much divergence of opinion among naturalists, but the division into two great suborders, the *Rhopalocera*, or butterflies, and the *Heterocera*, or moths, is well established in usage.

The *Rhopalocera* contains six families:

I. *Nymphalidae* ("Brush-footed Butterflies").—The front pair of legs greatly reduced in size, tarsi of the male with but one joint, of the female with five, but without claws, the pupa suspended by the cremaster. There are eight subfamilies in this group, more than 250 genera, and about 5,000 species known at the present time. Among these are some of the largest and most splendidly colored butterflies, which are known, as well as some of the smallest and most obscurely colored forms. The family is represented in all parts of the globe.

II. *Erycinidae* ("Metal-marks").—The female has the first pair of legs weakly, though perfectly developed. The coxa of the foreleg of the males is spined, and the tarsi are unjointed and without claws. There are over 60 genera and fully 1,000 species in this group. The butterflies composing it are generally small, but gaily and curiously colored. The metropolis of the family is found in the hot lands of the New World, though it is also represented in the eastern hemisphere.

III. *Lycenidae* ("Blues," "Coppers," and "Hair-streaks").—The fore legs of the male are aborted, the tarsus having but a single joint terminated by a single claw. There are over 2,000 species known. The butterflies are generally small. The upper sides of the wings are prevalently some shade of blue, bronzy green, or copper, though there are some species, especially in Africa, yellow, red, or white.

IV. *Pieridae* ("Whites," "Sulphurs," and "Orange-tips").—The six legs are well developed in both sexes and the feet have two hooks or claws at the end. There are about 1,200 species known to science. The "cabbage butterfly" and the "common sulphur" of the clover fields are fair representatives.

V. *Papilionidae* ("Swallow-tailed butterflies").—The six legs are well developed. The claws are simple. About 1,000 species belong to this family, among them some of the largest and most splendid tropical insects.

VI. *Hesperiidae* ("Skippers").—The six legs are perfect. The claws are short and thick. The bodies are relatively robust. In flight the insects are very quick and powerful, hence the common name. The butterflies are generally small, though there are some quite large species.

There are about 13,000 species of butterflies which have been named and described. It is probable that when we shall have explored the entire earth the total number of existing species may be found to be 18,000.

The *Heterocera*, or moths, may be divided into about 60 families, of which 43 are represented in North America. The families which have the largest number of species in North America are the *Noctuidæ*, or "owl-moths," the *Geometridæ*, or "measuring-worm moths," the *Saturniidae*, or "wild silk-moths," the *Arctiidae*, or "tiger-moths," the *Sphingidae*, or "hawk-moths," the *Tortricidae*, or "leaf-rollers," and the *Pyralidae*. More than 7,000 species of moths are known to occur in the United States and Canada, and probably more than 100,000 species at present exist upon the globe.

The most important of all the *Lepidoptera* from a commercial standpoint is the silk-moth (*Bombyx mori*), which was introduced into Europe from China by way of India, and at an early date was brought to the New World.

Lepidosiren, the American genus of *Dipnoi* (q.v.) or lung-fishes, closely resembling the African genus *Protopterus*, but having a more eel-like form, smaller scales and the paired limbs reduced to mere filaments of no use in locomotion. The single species *Lepidosiren paradoxa* was discovered by the Austrian naturalist Natterer in the tributaries of the upper Amazon in 1837. For fifty years the species

LEPIDOSTROBUS — LEPROSY

was known from only two or three museum specimens, but in 1887 was re-discovered in abundance in Paraguay by an Italian zoologist, and since then has been the object of several expeditions which have made it well known. It lives in the sluggish, vegetation-choked streams and lakes of that region, the natives of which spear it in large numbers for food. Its large eggs, more than a quarter of an inch in diameter, are deposited in underground nests where they are guarded by the males, whose ventral fins become densely villous and serve as accessory respiratory organs at this time. On the approach of the dry season the muscles of the tail undergo fatty degeneration and the fish retires to a mucus-lined "cocoon" in the mud at the bottom of a burrow sealed at intervals of 3 or 4 inches by plates of mud perforated by two or three small openings. In these retreats the "lolachs," as they are called by the Indians, remain until the rains again convert the baked earth into mud. The lepidosiren feeds on large aquatic snails, conchæ, and roots.

Lepidos'trobus (Gr. "whirling scale"), a cone from the coal measures, usually found in seams or nodules of clay-ironstone, and often compressed. They consist of a central axis surrounded by imbricated scales or bracts, each containing a sporangium (spore-case). They have been found united to the tip of the branches of *Lepidodendron*, and this shows that they were the fruit of that genus.

Lepidos'teus. See GAR.

Lep'idus, Marcus Æmilius, Roman triumvir: d. Circeii 13 B.C. He became prætor 49 B.C., consul with Julius Caesar in 46, and in 44 was appointed by Caesar to the government of Narbonese Gaul and Nearer Spain. He was in Rome at the time of Caesar's death, and joined Mark Antony. In 43 he united with Antony and Octavianus to form the triumvirate, obtaining Spain and Narbonese Gaul in the division of the empire. After the battle of Philippi (42) a re-division took place, in which Lepidus received Africa, where he remained till 36, when he was summoned by Augustus to assist him against Sextus Pompey. He then tried to seize Sicily, but was overcome by Augustus, who deprived him of his triumvirate, and banished him to Circeii, where he lived under strict surveillance.

Lepor'idae, a family of rodents comprising the rabbits and hares (q.v.). With the *Lagomyidae* it constitutes the suborder *Duplicidentata*, distinguished from all other rodents by having two pairs of upper incisors, of which the second is much reduced in size and placed immediately behind the first or larger pair. The hind-legs are much longer than the fore-legs and are well adapted by their structure for the leaping mode of locomotion affected by these animals; the tibia and fibula are completely ankylosed and articulate with the calcaneum by a pulley-like surface, thus combining great strength with great freedom of movement in one plane. The family is now cosmopolitan, but no species is indigenous to Australia. The genus *Lepus* is practically co-extensive with the family.

Leprosy, a term very vaguely used by medical and other writers to denote a disease, *Lepra tuberculosa*, which appears to have prevailed from the earliest time down to the present. The affection is identical with the *elephantiasis* of the Greeks and the *lepra* of the Arabians, which is altogether different from the *elephantiasis* of the Arabians and the *lepra* of the Greeks. The most prominent symptoms of the disease are as follows: dusky red or livid tubercles of various sizes on the face, ears and extremities; thickened state of the skin with diminution of its sensibility; falling off of the hair, except that of the scalp; hoarse, nasal or lost voice; ozæna; ulcerations of the surface and extreme fetor. The tubercles vary in size from that of a pea to an olive. Hands, feet and face are generally first affected.

In modern times three kinds of leprosy are recognized. In the first variety the whole body becomes white and scaly, without much interference with the general health. This is the true Biblical leprosy, and it is rare nowadays. The second variety makes the victim insensible to pain in the hands and feet in its earlier stages, and later on in the arms and legs. It is known as anæsthetic leprosy. The sufferer from this form of the disease is much troubled with dysentery, and when the disease is advanced his hands and feet are liable to slough off. The third variety of leprosy is known as the tubercular form. It is distinguished by horrible swellings of loose skin, which becomes discolored. This is the commonest modern variety of the disease and the one most repulsive.

In Palestine and the countries immediately east of it leprosy existed until the dispersion of the Jews in the 1st century of the Christian Era. As the power of the Roman Empire declined in the west of Europe a strong tide of emigration from the Levant set in. The plague of leprosy spread with the teaching of Christianity until no country in Europe was free from it. Between the 6th and the 15th centuries leprosy was by far the most dangerous and infectious disease of which any account has come down to us.

To be a leper was to be an outcast beyond hope of any solace but the grave. All the larger towns in Europe had a place specially set apart for its lepers. This reservation was shunned as if it were the mouth of a burning hell. A boundary line was made, beyond which no leper could venture, except at the risk of instant death. If a healthy stranger unwittingly wandered too near the leper's camp he was remorselessly thrust into it and made to share the lot of those previously afflicted. Food was furnished to these leper camps by the town authorities. The provisions intended for the use of the lepers were left on some exposed hill, selected for that purpose, during the daytime, and removed by the inmates of the camp at night. No office, no matter how exalted, served to keep a sufferer from leprosy from universal ostracism.

In the sparsely settled country districts, solitary lepers abounded. Each one wandered about by himself in the unfrequented woods and uninhabited waste places. The rigorous compulsion of the villagers compelled him to wrap himself in a sheet so that only his eyes

LEPSIUS — LEPUS

were exposed. He must carry a bell in his hand and ring it in order to warn wayfarers of his approach. Whenever the dismal tinkling of the leper's bell was heard, the inhabitants fled in terror of their lives. The unfortunate victim supported life as best he might by roots and berries, and by the occasional offerings of charitable persons left where he could find them.

At an early period in the history of the Christian Church efforts were made to alleviate the sufferings of lepers. An order of Saint Lazarus was formed as early as 72 A.D., taking its name from Lazarus, the beggar who ate the crumbs which fell from the rich man's table. Later on, in the 12th century, a military order of Lazarus was founded by the Knights Hospitallers. When these knights were driven out of Palestine they made France and afterward Sicily their headquarters. Numerous lazarettos were established by them in the principal cities of Europe. For many years the grand master of this order was required to be a leper. In civil law the leper was treated as one dead. His property passed to his heirs, his wife was free to marry again, and on his departure for the lazaretto prayers for the dead were repeated over him, and a shovelful of earth was thrown after him to make the ceremony complete.

With the progress of civilization leprosy gradually disappeared from every part of Europe except Norway. Lazarettos gradually fell into disuse, and only the name of leper remained as a by-word to express social and moral contamination. Great Britain was one of the last countries to cut clean of leprosy. As late as the 15th century, 250 leper hospitals were in existence there. The government, as well as other European governments, has practically banished the disease, by careful surveillance. In British America the disease still lingers in New Brunswick. In the hospital for lepers at Tracadie there have been a score of cases regularly for many years.

In the United States leprosy has existed since the Revolution and probably will continue to exist. Leprosy hospitals in secluded spots are maintained in San Francisco, New Orleans, and New York, and cases are always found here in numbers from two or three to a score. In the Philippines at the time of the American occupation there were 15,000 cases in the islands, but by the census of 1902, only about 5,000 cases were reported. The disease was brought to Manila originally from Japan about 200 years ago.

The most celebrated leper colony or settlement in the world is that on the island of Molokai in Hawaii; but the conditions there have been much exaggerated. Molokai lies about 25 miles from the island of Oahu, and about 56 miles from Honolulu. Its native name is Ka-ania-pali, a land of precipices. It is 40 miles long, seven miles broad, and has an area of a little more than 200,000 acres. The leper settlement on the elevated, grassy plain of Kalaupapa has an area of 8,000 acres. This plain is bounded on three sides by the ocean, and on the landward side by perpendicular cliffs. There is always a delicious blending of warmth and coolness in the air, which indisposes one for mental and physical effort and soothingly induces a condition of blissful and tranquil repose.

The whole number of lepers at the Molokai settlement in 1902, was officially reported at 1,191, viz.: 741 males and 450 females. There would be, therefore, nearly seven acres of productive soil for every member of the settlement. There are hospitals, dispensaries, churches, and comfortable cottages for the accommodation of families; these cottages are well ventilated, abundantly supplied with fresh water and kept in good condition. Cottage residents requiring medical treatment are attended at their own homes by the resident physician. Every man, woman and child may draw 21 pounds of fresh beef every week, a liberal supply of taro, flour or bread, rice, tea, sugar, salt, tobacco, and matches, and as much good clothing as required. A sum of money is paid to those who do not draw the full ration, which enables them to purchase articles not included in the regular supply.

Whether leprosy can be cured is a question. The administration of tonics and astringents has appeared to give good results. The use of iodides and mercurial preparations have also been tested, as well as the tincture of cantharides; but all of these remedies produce more or less identical effects—that of a temporary amelioration of the condition of the patient, but without well-founded hopes of anything approaching a genuine cure. A well known specialist believes in the use of camphor, in the form of a syrup, as one of the best methods of combating the disease; and his enthusiasm leads him so far as to state that he is convinced that leprosy is curable, if not allowed to pass certain limits, and that even those in the worst stages will derive marked benefits from the camphor treatment. Temporary alleviation has frequently been obtained by various methods, as, in a disease like leprosy, any remedy which tends to improve the state of the blood and the general health will, no doubt, have its temporary ameliorating effect upon the malady itself. Many years of careful study and of patient and conscientious application of all methods of treatment have satisfactorily demonstrated the incurability of the disease, and the most that can be done is to alleviate, as far as possible, the physical suffering and mental distress.

WILL M. CLEMENS,
Editorial Staff, 'Encyclopedia Americana.'

Lepsius, lēp'sē-oos, Karl Richard, German Egyptologist: b. Naumburg 23 Dec. 1810; d. Berlin 10 July 1884. After studying philology at Leipsic, Göttingen, and Berlin, he published his first work 'De Tabulis Eugubinis' (1833) and thereupon removed to Paris. In 1835 he visited Italy and took up his residence at Rome. He subsequently went to London and projected with Bunsen a large work on ancient Egypt. He started in 1842 on the first of his two visits to Egypt. His life henceforth was that of an ardent Egyptologist, and honors were showered upon him. He was professor in the Berlin University, director of the Egyptian section of the Royal Museum, director of the Royal Institute, head of the Royal Library, etc. He was author of a large number of important works on Egyptian antiquities.

ing several bright stars, among them Alpha and Beta Leporis.

Le Queux, lē kū, William, English novelist: b. London, England, 2 July 1864. He studied art in Paris and was subsequently a journalist there, but presently returned to London and in 1888 was a parliamentary reporter for the 'Globe,' and its sub-editor 1891-3. In 1900 he was appointed English consul to San Marino. Among his numerous fictions are: 'Guilty Bonds' (1890); 'Sinned Against' (1891); 'The Great War in England' (1892); 'Stolen Souls' (1894); 'Whoso Findeth a Wife' (1897); 'The Day of Temptation' (1897); 'Scribes and Pharisees' (1898); 'Wiles of the Wicked' (1900); 'In White Raiment' (1900); 'The Tickencote Treasure' (1902).

Leray, lē-rā', Francis Xavier, American Roman Catholic bishop: b. Châteaugiron, France, 1825; d. France 1887. He was educated at Rennes, but in 1843 crossed the Atlantic and settled at Baltimore. He went through the ordinary theological course under the direction of the Sulpicians and was admitted to the priesthood 1852. He was a chaplain in the Confederate service during the war and afterward returned to Vicksburg, and while the plague of 1867 raged, was always at hand to comfort and assist the sufferers. In 1873 he was consecrated to the see of Natchitoches, La., and 10 years later promoted to the archiepiscopal chair of New Orleans.

Lerdo de Tejada, Sebastian, sā-bäs'tē-än lär'dō dā tā-hä'dā, Mexican statesman: b. Jalapa, Mexico, 25 April 1825; d. New York 21 April 1889. He was educated at the College of San Ildefonso, Mexico, was admitted to the bar in 1851 and was appointed a judge of the supreme court in June 1857. He was minister of foreign affairs in 1857; member of Congress in 1861-2 and in 1862-3; and accompanied President Juarez in 1863-7, during which time he was successively minister of justice and minister of foreign affairs. He was elected chief justice of the supreme court in December 1867, and on the death of Juarez, 18 July 1872, succeeded to the presidency, and in the following November was elected to that post. In 1876 he was again candidate to succeed himself, and after a doubtful election was declared re-elected by Congress. This action resulted in a revolution and Lerdo was forced to leave the country. He lived in retirement in New York city till his death.

Lermontoff, lér'món-tōf, Mikhail Yuryevitch, Russian poet: b. Moscow 3 Oct. 1814; d. 15 July 1841. He was educated at the University of Moscow, became a hussar of the imperial guard in 1834, and in 1837 wrote his lines 'On the Death of a Poet,' in which he denounced the killing of Pushkin in so vigorous a fashion that he was sent to serve in the army of the Caucasus as an ensign. In 1838 he was pardoned and returned, but later was killed in a duel by one Martynoff, who imagined himself caricatured in Lermontoff's novel, 'A Hero of Our Time.' Lermontoff was a Byronic figure, abounding in ridicule and satire. The Russians rate him as their greatest poet after Pushkin. Had he lived longer he would probably have produced more extended and even

more valuable work. His chief poem is 'The Demon,' which has been translated into English by Stephen (1875). 'The Circassian Boy' and 'A Hero of Our Time' also exist in English renderings, the former by Conant (1875), the latter by Pulski (1854) and Nestor-Schurmann (1899).

Lernæ'a. See FISH-LICE.

Le Rossignol, lē rō-sēn-yōl, James Edward, American educator: b. Quebec, Canada, 24 Oct. 1866. He was graduated at McGill College and University, Montreal, in 1888; taught in the public schools of that city 1888-9; from 1889 to 1892 was a graduate student in Germany; in 1892-4 was professor of psychology and ethics in Ohio University; and since then has been professor of economics at the University of Denver. During 1900 he was special lecturer in economics at McGill College and University. He has written much on economical subjects, and has published 'Monopolies, Past and Present' (1901).

Leroux, Charles Marie Guillaume, shärl mä-rē gē-yōm le-roo, French painter: b. Nantes (Loire-Inférieure) 1814; d. 1895. He studied law and entered legal practice; but abandoned the bar for art, and after study with Corot, became a landscape artist. Among his canvases are: 'Souvenir de Fontainebleau'; 'Fête in Haut-Poitou'; 'The Erdre in Winter'; 'Dunes des Chênes Verts.'

Leroux, Frédéric Etienne, frā-dē-rīk ä-tē-ēn, French sculptor: b. Ecouché (Orne) 3 Aug. 1836. He studied with Jouffroy and at the Beaux-Arts, became an exhibitor at the Salon in 1863, obtained a medal of the second class at the Paris exposition of 1878, and a silver medal at that of 1889. Among his best known works are: 'Demosthenes on the Shore'; 'Joan of Arc'; 'Marchand de Violettes'; 'Bouquetière.'

Leroux, Hector, French painter: b. Verdun 27 Dec. 1829. He was a pupil of the Beaux-Arts and of Picot, in 1857 obtained by his 'Lazarus' the second Prix de Rome, traveled in Greece and Asia Minor, and became known for his reposeful and dignified scenes from the ancient life of Greece and Rome. Among his works are: 'A New Vestal' (1863); 'Funeral in the Columbarium of the House of the Cæsars' (1864); 'Messalina' (1868); 'The Burial of Themistocles' (1876); 'The Fall of Herculaneum' (1881).

Leroux, Louis Eugène, lōo-ē è-zhān, French painter: b. Paris 28 Sept. 1833. He studied with Picot, became known for his genre-scenes derived from Breton life, and painted, among his more important works: 'Le Nouveau-Né' (in the Luxembourg Gallery); 'Avant l'Ensevelissement'; 'La Prière'; and 'Avant la Confession.'

Leroux, Robert Henri, rō-bär öñ-rē (called HUGUES), French journalist and author: b. Havre 1860. He became a journalist at Paris, where he wrote for the *Temps*, *Matin*, *Figaro*, *Journal*, and other newspapers, and published two works on Russia, 'La Russie Souterraine' (1885), and 'L'Attentat Sloughine,' a story of the Nihilists. He has visited the United States as lecturer before the Cercle Français de l'Harvard. His further works in-

LE ROW — LESBOS

clude: 'L'Autre France' (1900), a drama, with Decourcelle; the works of fiction, 'Un de Nous' (1886); 'Le Maitre de l'Heure' (1897); 'Le Fils à Papa' (1900); and the studies and sketches, 'Au Sahara' (1891), 'Portraits de Cire' (1891), 'En Yacht' (1892), 'Marins et Soldats' (1892), 'Notes sur la Norvège' (1894), and 'Nos Filles: Qu'en Ferons-Nous?' (1898).

Le Row, lē rō, Caroline Bigelow, American educator: b. New Brighton, Staten Island, N. Y., 28 Dec. 1843. She was graduated at the Boston Normal School, and took courses in physical culture, voice culture and elocution under private instruction. In 1865 she entered the profession of teaching, which she has since followed, her present position (1904) being with the Girls' High School, Brooklyn, N. Y. She has published: 'Duxberry Doings'; 'A Fortunate Failure'; 'How to Teach Reading'; 'A Practical Reader'; 'Practical Recitations'; 'Columbian Speaker'; 'English as She is Taught' (1902); 'The Young Idea' (1902).

Leroy, lē-roï, William Edgar, American naval officer: b. New York 24 March 1818; d. there 10 Dec. 1888. In 1832 he entered the navy as a midshipman and served as a lieutenant on the Princeton during the Mexican War. He served in the United States navy during the Civil War also, doing good service on several important occasions, became a commodore in 1870 and a rear-admiral in 1874. He commanded the South Atlantic squadron 1876-9 and retired from active service in 1884. On account of his courtly manners and general fastidiousness he was often styled "the Chesterfield of the Navy."

Leroy-Beaulieu, lē-rwā bō-lē-ē, Henri Jean Baptiste Anatole, French historical writer: b. Lisieux, Calvados, 1842. He is a brother of Pierre Paul Leroy-Beaulieu (q.v.). In 1881 he was appointed to the chair of modern history in the Ecole Libre des Sciences Politiques, and in 1887 was elected to the Academy of Moral and Political Sciences. He contributed extensively to the 'Revue des Deux Mondes,' and published in 1887-9 the important work, 'L'Empire des Tsars et les Russes,' a study of Russian history, politics, and civilization, based partly on direct observation. Others of his publications are: 'La France, la Russie, et l'Europe' (1888); 'La Révolution et le Libéralisme' (1890), 'Israël chez les Nations' (1893).

Leroy-Beaulieu, Pierre Paul, pē-är pōl, French economist: b. Saumur, Maine-et-Loire, 9 Dec. 1843. He was educated at the Lycée Bonaparte and the Ecole de Droit of Paris and the universities of Bonn and Berlin; became a journalist at Paris; wrote his 'De l'Etat Moral et Intellectuel des Populations' 'Ouvrières' (1868), crowned by the Academy of Moral and Political Sciences; assisted in founding the Ecole Libre des Sciences Politiques; and was appointed professor of finance there in 1872. In 1880 he became professor of political economy in the Collège de France. He established in 1873 'L'Economiste Français,' which he has continued to edit. In 1878 he was elected to the Academy of Moral and Political Sciences. Among his further writings are: 'Les Guerres Contemporaines' (1853-66; 1868-9); 'Traité de

la Science des Finances' (1877; 5th ed. 1891); and 'Précis d'Economie Politique' (1888; 3d ed. 1891).

Léry, Jean de, zhōñ dē lä-rē, French Calvinist preacher: b. La Margelle, France, 1534; d. 1601. In 1556 he was sent from Geneva to preach at Rio Janeiro, Brazil, where French colonies had been established by the Huguenots, and was the first Protestant minister to preach on the American continent. He and the preachers who accompanied him were obliged to return to France, owing to a bitter misunderstanding which arose between them and those who employed them. Léry has left an account of his travels in the west under the title 'Histoire d'un Voyage fait en la Terre du Brésil' (1578).

Lesage, Alain René, à-lāñ rē-nā lé-sāzh, French novelist and playwright: b. Sarzeau, near Vannes, 8 May 1668; d. Boulogne-sur-mer 17 Nov. 1747. He studied law in Paris and became an advocate, but soon afterward turned all his attention to literature. He made many fruitless efforts after recognition and success, principally by translating from the Greek and Spanish. At length two plays of his, 'Crispin Rival de Son Maître' (1707) (adapted from a Spanish piece of Mendoza's), and 'Tuscaré' (1708), a satire on the financiers of his day, had a genuine success. But he gained even greater praise and reputation from his comic romance, 'Le Diable Boiteux' (1707). This was indeed merely an imitation of a Spanish tale of Guevara, which he completely Galicized so as to direct its point against the Pietism which characterized the last period of Louis XIV.'s reign. But his greatest work was 'Gil Blas de Santillane' (1715). To his eternal disgrace Voltaire as well as many Spaniards jealous for their country's honor asserted that this novel was a bare-faced plagiarism from a Spanish original. In 'Gil Blas' the wit of the author is triumphant and the surprises and adventures of human life, with all the ups and downs of fortune, are made to rouse our sense of humor as well as our keenest interest, and to dazzle our fancy by the swiftness and variety of their changes. The work is, of course, destitute of high ideal and all moral aim, but it has been compared with those of Rabelais and La Fontaine, and its hero was certainly the precursor of Figaro. The most memorable of Lesage's other romances are 'Les Aventures de Guzman d'Alfarache' (1732), an imitation of a Spanish romance of Mateo Aleman, and 'Le Bachelier de Salamanque' (1736), the latter the production of his declining years, and highly valued by him. But his most numerous works were vaudevilles, and comic operas (101 in all). The Academy revenged itself on him for the graceless levity and irreverence toward the learned professions which he exhibited in his works, by refusing to elect him to their number. But they failed to check the growth of his fame. His influence was first spread in England through Smollet, and in France through Balzac. A full edition of his works was published in Paris in 1828. Consult: Claretie, 'Le Roman en France au début du XVIII. Siècle, Lesage Romancier' (1890); Barbaret, 'Lesage et le Théâtre de la Foire' (1887).

Lesbos, lēz'bōs. See MITYLENE.

LESCHETIZKY—LESLIE

Leschetizky, lĕsh-ĕ-tĕs'ki, Theodore, Austrian pianist: b. Lemberg, Austria, 1831. He received his musical education in Vienna, and after a successful concert tour in 1864 was made professor of the pianoforte at the conservatory of St. Petersburg, where he turned out many illustrious pupils. In 1878 he returned to Vienna with an ever-increasing reputation. As a pianist he is remarkable for delicacy of touch and a magic power of expression. As a composer he has published some very elaborate pieces for the piano, some songs, and an opera ('Die erste Falte') (1867). Perhaps the most famous of all his pupils is Paderewski (q.v.).

Lesghians, lĕs'gi-anz, a Tartar people professing Muradism, a form of Mohammedanism established by a native prophet about 1830. They inhabit the Eastern Caucasus, and form the chief portion of the inhabitants of western Daghestan. They were among the most stubborn of the Caucasian peoples in their resistance to the Russians.

Lesley, lĕs'li, J. Peter, American geologist: b. Philadelphia 17 Sept. 1819; d. Milton, Mass., June 1903. He was graduated at the University of Pennsylvania in 1838, for the next three years was engaged as assistant in the first geological survey of Pennsylvania. In 1844 he was graduated at the Princeton Theological Seminary and licensed as a minister. Visiting Europe, he made foot-journeys through several countries, and for a while studied at the University of Halle. From 1845 to 1848 he labored for the American Tract Society among people in the mountain districts of Pennsylvania, and then served two years as minister of a Congregational church at Milton, Mass., resigning on account of a change in his religious views. Returning to Philadelphia, he resumed his geological researches, extending his investigations throughout the coal, oil, and iron regions of this country and Canada. In 1855 he became secretary of the American Iron Association; in 1858 secretary and librarian of the American Philosophical Society; and State geologist of Pennsylvania in 1874. He was also professor of geology at the University of Pennsylvania 1872-8, and there in 1886 was appointed emeritus professor. In 1863 he went to Europe to examine the Bessemer iron-works for the Pennsylvania Railroad Company, and in 1867 was appointed by the United States Senate a commissioner to the Paris Exposition. He edited many works, published numerous scientific papers in various journals and reports, and also wrote: 'A Manual of Coal and Its Topography' (1856); 'The Iron Manufacturer's Guide' (1858); 'Man's Origin and Destiny from the Platform of Sciences'; 'Historical Sketch of Geological Explorations in Pennsylvania' (1876); and 'Paul Dreifuss, His Holiday Abroad' (1882).

Lesley, John, Scottish prelate and historian: b. Scotland 29 Sept. 1527; d. near Brussels, Belgium, 31 May 1596. He was educated at King's College, Aberdeen, and in 1554 became professor of canon law there. A firm friend of Mary, Queen of Scots, and by her appointed bishop of Ross, he was concerned in the scheme for her marriage to the Duke of Norfolk, and in the consequent rebellion in the north of England, and was imprisoned in the

Tower. While there he wrote 'Pie Consolations.' When released in 1573 he crossed to the Continent, and in 1593 became bishop of Coutances in Normandy. His chief production is a history of Scotland (1578), in 10 books, 7 in Latin and the last 3 Scottish dialect.

Leslie, Charles Robert, English painter: b. London, England, 19 Oct. 1794; d. there 5 May 1859. His parents were Americans, the father being a watchmaker of Philadelphia, and to that city they returned with the boy in 1800. There he attended school, and was afterward apprenticed to a bookseller; in 1811 went to England and studied with Allston, West, and others; was elected associate of the Royal Academy in 1821, and in 1826 to full membership. He first adopted a style in large historical subjects, but his genius led him into historical genre of a humorous character, in which he excelled alike in conception and execution, and in which his gentle humor was as pervasive as his finished manner. He was first brought into wide notice by his 'Sir Roger de Coverley Going to Church' (1819). To this period belong his portrait of Washington Irving and the illustrations which he designed for that author's 'Sketch-Book' and his 'Knickerbocker's History of New York.' Leslie's election as an associate of the Academy was secured by 'May-day Revels in the Time of Queen Elizabeth.' In 1824 he visited Sir Walter Scott at Abbotsford and painted his portrait. He was elected professor of drawing at the United States Military Academy, West Point, in 1833, accepted the position, but in a few months gave it up and returned to England. In 1838, at Windsor, he painted 'The Queen Receiving the Sacrament after the Coronation.' From 1848 to 1852 he was professor of painting at the Royal Academy. His principal pictures illustrate scenes from the works of great authors, among his strongest traits delicate perception of character and of womanly beauty being observable. His best known paintings include: 'Sancho Panza in the Apartments of the Duchess' (1828); 'Uncle Toby and the Widow Wadman' (1831); 'The Taming of the Shrew' (1832); and 'The Dinner at Mr. Page's House' (1838). He published a volume of lectures as a 'Handbook for Young Painters' (1855); 'The Memoirs of Constable' (1865); an unfinished 'Life of Reynolds' (1865); and 'Autobiographical Recollections' (1860).

Leslie, Eliza, American author: b. Philadelphia 18 Nov. 1787; d. Gloucester, N. J., 1858. Her girlhood was spent partly in London, England, where her brother, Charles Leslie (q.v.), afterward became distinguished as an English artist. She returned to the United States in 1799, and the rest of her life was nearly all passed in her native city. She first became famous by her 'Seventy-five Receipts for Pastry, etc.' (1827), followed by 'The Domestic Cookery Book' (1837), 40,000 copies of which were sold; 'The Home Book' (1840); and 'The Ladies' Receipt Book' (1846). She had, however, soon after the success of her first work, begun to write juvenile and other works, and for a generation was one of the most popular of American prose writers. Her books are mainly, though not invariably, written to enforce moral instruction, and among them are: 'The American Girls' Book' (1831); 'Stories for Helen';

LESLIE — LESSING

‘Kitty’s Relations’; ‘Leonilla Lynmore’; ‘The Maid of Canal Street’; ‘The Dennings and their Beaux’ (1851); ‘Mrs. Washington Potts’; and ‘The Behavior Book’ (1853). She edited for many years ‘The Gift,’ a popular annual for young women.

Leslie, Frank (assumed name of Henry Carter), American publisher and journalist: b. Ipswich, England, 1821; d. New York 10 Jan. 1880. He was educated at Ipswich; entered a mercantile house at 17; developed artistic abilities, and under the name of Frank Leslie contributed sketches to the ‘Illustrated London News.’ The success of these led to his giving up commercial pursuits to become superintendent of engraving for that paper. In this position he produced valuable inventions, and made himself master of technicalities. Coming to the United States in 1848, he followed his profession here, and in 1854 founded the ‘Gazette of Fashion’ and the ‘New York Journal.’ In 1855 he began the publication of ‘Frank Leslie’s Illustrated Newspaper’ (now ‘Leslie’s Weekly’), following these with the ‘Chimney Corner,’ the ‘Boys’ and Girls’ Weekly,’ the ‘Budget of Fun,’ and others. In 1867 he was appointed commissioner to the Paris Exposition, where he received a prize for his services to art. He married Miriam Florence Folline, of Louisiana, and she, having taken at his death, by legislative act, the name of Frank Leslie, successfully continued the business, from which she finally withdrew in 1900.

Les Misérables, là mē-zā-rā-bl, a novel by Victor Hugo (q.v.), giving a comprehensive view of Parisian life, chiefly among the lower orders, during the 19th century. It was published 3 April 1860, having been translated previously into nine languages. It has been translated since into 12 other languages.

L’Espinasse, Julie Jeanne Éléonore de, zhü-lé zhan él-ä-ö-nör là-pi-nas, French letter writer: b. Lyons November 1732; d. Paris 22 May 1776. She was an illegitimate daughter of Madame D’Albon, and on the death of her mother she went to live with the Marquise De Vichy, the legitimate daughter of Madame D’Albon, and in 1754 became the companion of Madame Du Deffand (who had already become blind), at the urgent request of the latter. This position she occupied for about 10 years; but the jealousy and selfishness of Madame Du Deffand rendered her situation very uncomfortable. She gained the friendship of all the élite of Madame Du Deffand’s society, such as Marmontel, D’Alembert, and Turgot; and when the separation between the two ladies at last occurred her friends all adhered to her. Her earliest letters are addressed to a Spanish Marquis, Gonsalvo de More, and the later ones to Count de Guibert, a mediocre poet and essayist. They are infused with passionate devotion and were published by the widow of Guibert in 1800, and appeared in English in Boston in 1903. Consult: Asse, ‘Mlle. de Lespinasse et Mme. du Deffand’ (1877).

Lesquereux, là-kē-ré, Leo, Swiss-American palæontologist: b. Fleurier, Neuchâtel, Switzerland, 18 Nov. 1806; d. Columbus, Ohio, 25 Oct. 1889. He was educated at the Academy of Neuchâtel, at Weimar, and at the University

of Berlin; was principal of the College of Chaux-de-Fonds (Switzerland) in 1829-34; made a special study of peat; and was appointed by the Neuchâtel authorities to examine the peat bogs of that canton. In 1844 he received from the Neuchâtel government a gold medal for his treatise, ‘Directions for the Exploration of Peat Bogs.’ In 1848 he came to the United States; was for a short time assistant to Louis Agassiz at Cambridge; and later became assistant to W. S. Sullivan (q.v.), in the study of American bryology, at Columbus, Ohio, where he resided until his death. He made particular investigation of the coal formations of the United States, more especially of the Pennsylvania coal flora, and he became the chief American authority on fossil botany. He published with Sullivan: ‘Muscum Americanum Exsiccatum’ (1856; 2d ed. 1865), and ‘Icones Muscarum’ (1864); and with T. P. James ‘Manual of the Mosses of North America’ (1884). He also contributed (1880-4) three volumes on the coal flora to the Pennsylvania geological survey, which has been considered one of the chief American works on carboniferous plants; and three reports to the volumes published by the Hayden survey. He wrote more than 50 memoirs on scientific subjects. In 1864 he became a member of the National Academy of Sciences, and in 1888 of the Geological Society of London.

Lesseps, lē-sēps (Fr. lē-séps), Ferdinand, VICOMTE DE, French diplomat: b. Versailles 19 Nov. 1805; d. 7 Dec. 1894. He entered the diplomatic service in 1828, and after being consul at various places was ambassador to Madrid in 1848-9. In 1854 he went to Egypt at the invitation of the viceroy, Said Pasha; there sketched a plan for canalizing the Isthmus of Suez, and in 1856 published a report on the subject. This great work was at last begun in 1859, and was carried to completion under his supervision in 1869. (See SUEZ CANAL.) He also planned the unfortunate Panama Canal (q.v.), and after the company was dissolved in 1889, judicial proceedings were taken against Lesseps and other directors for maladministration of funds and bribery, and he was condemned to imprisonment. He was elected to the Academy of Sciences in 1875, and to the Académie Française in 1884. Among his writings are: ‘Mémoire à l’Académie des Sciences sur le Nil Blanc et le Soudan’; ‘Principaux Faits de l’Histoire d’Abyssinie’; ‘Lettres, Journal et Documents relatifs à l’Histoire du Canal de Suez’ (1875-81), crowned by the Academy; ‘Souvenirs de Quarante Ans’ (1887); and ‘Origines du Canal de Suez’ (1890). Consult biographies by Bertrand and Ferrier (1887) and by Smith (2d ed. 1895).

Les’sing, Gotthold Ephraim, German dramatist and critic: b. Kamenz, Upper Lusatia, Saxony, 22 Jan. 1729; d. Brunswick 15 Feb. 1781. He was a diligent student, who, according to his tutor, was a horse that needed double fodder. He went to Leipsic ostensibly for a theological training; but he gave his chief attention to general literature, and contributed some interesting articles to literary journals. His academic studies having been concluded at Wittenberg, he went to Berlin, where he was active as journalist and critic, and whether he returned (1758) after a two-years’ sojourn at Leipsic. In 1760 he became secretary to Gen-

LESSING — LESTER

eral von Tautentzien, governor of Breslau; and in that post continued for more than four years. His independence and fine sincerity led him to reject several opportunities of material advancement; as when he refused the chair of eloquence at Königsberg, because the tenure of it involved an annual eulogy of the king. In 1767 he became critic and director of the theatre at Hamburg which an association of wealthy merchants purposed establishing for the promotion of the national drama. The scheme shortly failed, and from 1770 until his death Lessing was librarian to the Duke of Brunswick at Wolfenbüttel, where he was valued only for the prestige he lent the little state. Lessing was the one who reformed German literature and set it on the way of national growth and progress. He became the foremost German writer of his time, and one of the more remarkable writers of all time, through his 'Minna von Barnhelm' (1767), the first national drama of Germany, and 'Laokoon' (1766), the best work of German criticism. 'Minna von Barnhelm' was an artistic presentation of contemporaneous life, and liberated the German drama from the slavish imitation of the French so exclusively preached by Gottsched. In it Lessing wished to rebuke not only the disposition toward aping the French, but also the indifference of the rulers, to the soldiers that had won the Seven Years' war; and to eliminate the provincial hate which then so often existed in Germany, especially that between Prussia and Saxony. In 'Laokoon' Lessing appears as one of the greatest of critics. His eagerness for truth is remarkable; his revelation of hypocrisies and falsehoods, fearless. His chief argument is that for the establishment of a clear distinction between the plastic arts and poetry, the basic difference being determined to be that while art presents objects in space, poetry presents actions in time. Not all its contentions may be admitted; but Herder, who published a criticism in disagreement with many of its points, yet read it through three times in an afternoon and following evening, and praised it in high terms. Macaulay said it made him wonder and despair; and Goethe, who was greatly indebted to its teachings, declared that by it "all previous criticism was thrown away like an outworn coat." His 'Nathan der Weise' (1772; in a good English rendering by E. Frothingham 1868) is the most celebrated of his dramas, and indeed perhaps the most generally familiar of all his writings. It was his ultimate answer to the theological controversialists who had begun their attacks with the publication by Lessing of an edition of portions of a manuscript work, obtained by him while in the ducal library, on the origins of Christianity and written by one Samuel Reimarus. To these 'Wolfenbüttler Fragmente' (1774-8) Pastor Goeze of Hamburg made the chief objection, and to Goeze Lessing gave his most elaborate rejoinders, such as 'Eine Parabel,' 'Axiomata,' and 'Anti-Goeze.' He does not defend Reimarus, but he does defend free inquiry, and opens up the field for later Biblical criticism and the study of the growth of Christian institutions. Lessing having been directed by the Brunswick government to discontinue the controversy, made a poetic statement of his views in 'Nathan der Weise,' a remarkable plea for religious tolerance, and a declaration that true religion is one of charac-

ter, not formula. The work has been criticised from the strictly dramatic viewpoint, but as a dramatic poem has been called one of the finest works of the 18th century. Others of Lessing's works are 'Emilia Galotti' (1772), a skilful tragedy; 'Briefe die Neueste Litteratur Betreffend' (1758), with Nicolai, which first directed German thought to the study of Shakespeare; 'Ueber das Wesen der Fabel' (1760); and the 'Hamburgische Dramaturgie,' dramatic reviews. "Lessing," said Goethe, "wished to disclaim for himself the title of poet, but his immortal works testify against himself." His battle against error in all domains had notable effect in Germany, and has not yet failed of an even wider stimulative interest. A collected edition of his works, prepared by various scholars, appeared in 1868-77. Consult the biographies by Sime (1877) and Zimmern (1878) in English, and by Stahr (1859) and Duntzer (1882) in German. See GERMAN LITERATURE.

Lessing, Karl Friedrich, kär'l frē'd'rīh, German painter, grand-nephew of G. E. Lessing (q.v.): b. Wartenberg, Silesia, 15 Feb. 1808; d. Karlsruhe, Baden, 4 June 1880. He was sent about 1822 to the architectural school of Berlin, to fit himself for an architect. After a severe struggle between duty and inclination, he yielded to his artistic inclinations and by the production of his 'Churchyard with Gravestones and Ruins' (1825) fixed his profession irrevocably. This picture produced a strong impression, and for a year or two the artist devoted himself to landscape; but coming under the influence of Schadow, established himself in Düsseldorf, and studied historical painting with enthusiasm and success. 'The Court Yard of the Convent—a Snow Scene,' is perhaps the most striking of all his landscapes. 'The Tyrant Ezzelin in Captivity refusing the Exhortations of the Monks' (1838), was his first important historical picture in the new style. It was followed by 'Huss before the Council of Constance' (1842), the 'Seizure of Pope Pascal II.,' the 'Martyrdom of Huss' (1850), now in New York, and many others, under the influence of which the school of Düsseldorf divested itself of the strictly Catholic spirit by which it was previously characterized, and adopted a bolder and more dramatic manner, and a greater freedom in the choice of subjects. Lessing, however, is distinguished from his associates by depth of thought, energy of expression, and vivid dramatic conception, at the same time that his pictures exhibit the hardness of outline and defective coloring peculiar to the Düsseldorf school. Consult Jordan, 'Ausstellung der Werke Karl Friedrich Lessings' (1880).

Lesson. See LECTORY.

Les'ter, Charles Edwards, American author: b. Griswold, Conn., 15 July 1815; d. Detroit, Mich., 29 Jan. 1890. He studied law in Mississippi, and was admitted to the bar, but afterward spent two years at the Auburn Theological Seminary, and was duly ordained. The pulpit, however, proved not more congenial to his tastes than the bar, and he employed his time chiefly with the pen. He was appointed United States consul at Genoa, 1842-7, and was afterward prominent as a journalist and political speaker. He published 'Glory and Shame of England' (1841); 'Condition and Fate of England' (1842); 'The Artist, Merchant, and

LESTER — LETCHWORTH

Statesman (1846); 'Life and Voyages of Americus Vespuccius' (1846); 'Artists of America' (1846); 'My Consulship' (1851); 'Our First Hundred Years' (1874-5); and translations of Alfieri's 'Autobiography' (1845); Massimo d'Azeglio's 'Challenge of Barletta' (1845), and Macchiavelli's 'Florentine Histories' (1846).

Lester, John Henry, American inventor: b. Montville, Conn., 27 Sept. 1815; d. Brooklyn, N. Y., 10 Jan. 1900. He was one of the earliest sewing-machine makers in the United States, and besides inventing a lock-stitch sewing-machine, he devised a wood-planing machine, and other labor-saving machines. In 1859-60 he established a wood-planing manufactory in Richmond, Va., and when the Civil War broke out was ordered by the Confederate government to alter arms for its army. Lester, being loyal to the North, withdrew from the firm and went to Washington, D. C., where he had an interview with President Lincoln. Nevertheless, his loyalty was suspected and he was sentenced to ten years' imprisonment by a military commission, but was freed after 20 months' confinement.

Lestocq, lës-tök, Jean Hermann, French physician and adventurer: b. Celle, Hanover, 29 April 1692; d. Livonia 12 June 1767. He was the son of a French Protestant surgeon who had left his native country on the revocation of the edict of Nantes, and when 21 went to Russia to seek his fortune. He was first employed by Peter the Great, but on account of his dissolute morals, was exiled to Kasan in 1718. Catharine I., on her accession in 1725, recalled him, and appointed him physician in the household of her second daughter Elizabeth. He soon gained an influence over the mind of this princess, and when the imperial title devolved upon Ivan VI., he persuaded her that the only way of saving her own life was to seize upon the crown. She yielded to his suggestions, made the young czar prisoner, and seated herself on his throne. Lestocq was then appointed privy councillor, which gave him the rank of general, physician in ordinary to her majesty, and president of the medical college. His prosperity lasted but a few years. Charged with treasonable projects, he was arrested, tortured, and exiled to Siberia. Peter III., on his accession, gave orders for his recall, and Catharine II. gave him an estate in Livonia.

Les'todon, a genus of fossil animals of Patagonia, allied to *Mylodon*, and distinguished by the possession of canine teeth. See GROUND-SLOTH.

Lestrangle, lës-tränj, Sir Roger, English journalist and pamphleteer: b. Hunstanton, Norfolk, 17 Dec. 1616; d. London 11 Dec. 1704. He was probably educated at Cambridge. In 1629 he accompanied Charles I. in his expedition against Scotland. In 1644 he formed a plan for surprising Lynn Regis, but was seized and condemned as a spy. He was, however, respited from time to time until he had been in prison four years, when he escaped to the Continent. In 1653 he returned to England, was licenser of the press from the Restoration until the close of the reign of James II., and edited the 'Public Intelligencer' in 1663, the London 'Gazette' in 1665, and the 'Observator' in 1681, the latter existing till 1687. He was author of a great number of coarse and virulent

political pamphlets, and translated Josephus, Cicero's 'Offices,' Seneca's 'Morals,' Quevedo's 'Visions,' and other works of ancient and modern writers.

Lesueur, Eustache, ès-täsh lë-sü-ér, French painter: b. Paris 19 Nov. 1617; d. there 30 April 1655. He was taught drawing by his father, a sculptor, and was afterward placed at the school of Vouet, where the Italian masters became his models. His masterpiece is the series of paintings executed for the Carthusian monastery in Paris in 1645-8. These pictures are now in the Louvre, and in twenty-two panels depict the principal scenes in the life of St. Bruno. In 1650 he painted for the corporation of goldsmiths the 'Preaching of the Apostle Paul at Ephesus,' which was presented to the chapter of Notre-Dame, but has been now removed to the Louvre. He did much in decorating the old parish churches of Paris and among his later productions are some mythological scenes in the Hotel Lambert. His works are distinguished by purity of line, careful execution and are conceived in a mood of profound feeling.

Le Sueur, Jean François, zhôñ frâñ-swâ, French composer: b. Drucat-Plessiel, near Abbeville, 15 Jan. 1760; d. Paris 6 Oct. 1837. At six he was placed at the musical school of the cathedral of Amiens, and after completing his studies was made director of music in the cathedrals at Séez, Dijon, etc., and in 1784 in the Church of the Innocents, Paris. In 1786 he became master in the Church of Notre Dame. He was afterward induced to compose for the theatre, 'Telemachus,' his first opera, being given with great success in the Théâtre Feydeau. From 1788 he devoted his time altogether to theatrical music. His opera 'La Caverne' was produced in 1793; 'Paul et Virginie' in 1794; 'Télémaque' in 1796; 'Les bardes' in 1804; and 'La Mort d'Adam' in 1809. He was made professor of music in the National Institute. In 1813 he became a member of the fourth class of the Institute; in 1814 composer to the king; and in 1817 professor of composition to the Conservatoire. His sacred music consists of 33 masses, and of oratorios and motets. He also wrote several works on musical subjects.

Letcher, John, American politician: b. Lexington, Va., 29 March 1813; d. there 26 Jan. 1884. He entered the practice of law in 1839, in 1850 was a member of the State constitutional convention of Virginia, and was a member of Congress in the immediate ante-bellum days. In 1859 he was elected to the governorship of Virginia. Though opposed to secession, he yielded to public opinion, and delivered the State troops and munitions to the uses of the Confederacy.

Letch'worth, William Pryor, American writer and philanthropist: b. Brownville, N. Y., 26 May 1823. From 1848 to 1869 he was a manufacturer and merchant in Buffalo, and retired from business to devote himself to benevolent work. In 1873 he became a member of the State Board of Charities, was its vice-president and for ten years its president, resigning from the board in 1890. In 1883 he was president of the National Conference of Charities, and in 1900 president of the first New York State Conference of Charities and Correction. In 1893 the University of New York conferred on him the degree of LL.D. "for distinguished services to

LETHARGY—LETTERS

the State." He secured the passage of the New York law for removal of children from almshouses, etc., and has done much for the insane, for epileptics, and for other unfortunate classes. He has published: "The Insane in Foreign Countries" (1889); "Care and Treatment of Epileptics" (1900); and numerous papers and reports on subjects connected with social science.

Lethargy, lēth'är-jī, an unnatural tendency to sleep, closely connected with languor and debility, and much resembling apoplexy in character. When awakened the person answers, but, ignorant or forgetful of what he said, immediately sinks into the same state of sleep. It may arise from a plethoric habit, from deficient circulation in the brain, or from nervous exhaustion of that organ. A poisoned state of the blood, or a suppression of urine, may induce the lethargic state. When it is the consequence of alcoholic intoxication, or of the action of narcotic drugs, it should be treated as for these conditions.

Lethbridge, Sir Roper, English statesman, scholar, and author: b. Devonshire 23 Dec. 1840. He was for many years prominent in educational and political movements in India, as professor in the Bengal educational department, and subsequently as political agent and press commissioner. He was a member of Parliament in 1885-6. Among his works are: "A Short Manual of the History of India" (1881); "High Education in India"; "A History and Geography of Bengal"; "The Golden Book of India"; etc. In 1890 he was created Knight Commander of the Indian Empire.

Lethe, lē-thē (Greek, *Lethe*, forgetfulness), the mythological River of Oblivion in the lower regions. The water had the power of making those who drank it forget their former existence. Souls before passing into the Elysian fields drank that they might have no recollection of their earthly sorrows; those who were destined to return to the upper world in new bodies, that they might forget the pleasures enjoyed in Elysium.

Letter of Credit. See CREDIT, LETTER OF.

Letter of Marque. See MARQUE, LETTER OF.

Lettering, the art of designing the letters of the alphabet for various commercial, mechanical, and artistic purposes, largely used in architectural work, sign painting, advertisement designing, engraving, printing and book plate and book-cover making. It may be said that practically all the lettering now used in architectural offices in this country is derived, however remotely it may seem in some cases, from the old Roman capitals as developed and defined during the period of the Italian Renaissance. Composition in lettering is almost too intangible to define by any rule. All the suggestions that may be given are of necessity laid out on merely mathematical formulæ, and as such are incapable of equaling the result that may be obtained by spacing and producing the effect solely from artistic experience and intuition. The final result should always be judged by its effect upon the eye, which must be trained until it is susceptible to the slightest deviation from the perfect whole. It is more difficult to define what good composition is in lettering than in painting or any other of the more generally accepted arts, and it resolves itself back to the same problem.

The eye must be trained by constant study of good and pleasing forms and proportions, until it appreciates instinctively almost intangible mistakes in spacing and arrangement. This point of "composition" is so important that a legend of most beautiful individual letter forms, badly placed, will not produce as pleasing an effect as an arrangement of more awkward letters when their composition is good.

Classic Roman Alphabet. From Marble Inscriptions in the Roman Forum.

Lettern. See LECTERN.

Letters, papers of correspondence between friends or those who are commercially or otherwise connected. The first letters of any importance which belong to literature are those of Cicero, in which are described not only his relations with the literary men of his age, his domestic sentiments and the memoranda of his own doings, but also the great political movements of his day. These letters are the most valuable documents extant in relation to the civil war, by which Roman republicanism was abolished and Roman imperialism inaugurated. Nothing can over-estimate their value unless we come to consider the letters of Pliny. The letters of Pliny illustrate the age of Trajan and are principally remarkable as introducing us to the growing power of Christianity in the Roman empire. At the same time they give us the most complete description of the Roman house that is found in Latin literature. The description of the mansion, grounds and garden of the wealthy Romans which this writer gives us is unexampled elsewhere. Passing from the letters of the ancient Romans we come to those of a later age, and we have the letters of Basil, Jerome and other Christian fathers. Among important relics of literature must be reckoned the letters of those who belong to the great period of the Renaissance. Memorable also are the letters of Erasmus, full of wit and humor, for in them the religiousness of the

LETTERS OF JUNIUS — LEUCÆMIA

divine is blended with the genial epigram of the man of letters. The correspondence of great men is always one of those sources of historic information whose importance cannot be overestimated. In looking over the whole field of European literature we find no more illuminating or refreshing fountain of information than in the letters of great men and women. Among these may be mentioned the letters of Madame de Sevigny, the letters of Lord Chesterfield, of Pope, Cowper, those of Gray, Shelley, Keats and Byron, and in our own time those of Fitzgerald. It has been said that the art of letter writing is a lost art, but so long as we have such beautiful and suggestive examples of epistolary correspondence as are contained in the writings of Robert Louis Stevenson and Fitzgerald it is absurd to say that the art of letter writing is one of the forgotten arts.

Lettres de Cachet, lët-r-dë-kä-shä, in France, a name given to the warrants of imprisonment issued by the kings before the Revolution. All royal letters (*lettres royaux*) were either *lettres patentes* or *lettres de cachet*. The former were open, signed by the king, and countersigned by a minister, and had the great seal of state appended. Of this kind were all ordinances, grants of privilege, etc. But these checks on arbitrary power did not exist with regard to *lettres de cachet*, also called *lettres closes*, or sealed letters, which were folded up and sealed with the king's little seal (*cachet*), and by which the royal pleasure was made known to individuals or to corporations and the administration of justice was often interfered with. It was not always for political reasons that *lettres de cachet* were obtained; sometimes private persons got troublesome members of their families brought to reason in this way. The lieutenant-general of the police kept forms of *lettres de cachet* ready, in which it was only necessary to insert the name of the individual to be arrested.

Letts, lëts, a Slavonic people closely akin to the Lithuanians, inhabiting a portion of Russia. Their language, along with the Lithuanian and Old Prussian (extinct), forms the Lettic or Lithuanian branch of the Indo-European family of tongues. The Letts number about 1,000,000.

Lettuce, lët'is, a genus (*Lactuca*) of hardy annual and perennial herbs of the order Composite. Less than ten of the one hundred recognized species, which are distributed mainly in the northern hemisphere, are in cultivation, and some botanists consider these to be merely forms of three or perhaps two species. They are characterized by opposite leaves of various forms, and white, yellow or blue flowers in heads which are arranged in small panicles. The only species used in America, the common garden lettuce (*L. sativa*) is an annual whose natural prototype is unknown, but is supposed to be *L. scariola*, an Asiatic species.

Lettuce is one of the oldest food-plants, having been used, it is said, by Persian royalty more than 2,000 years ago. To-day it is unquestionably the most widely used of all our salads, and has developed an innumerable host of varieties of great diversity of form. They are somewhat roughly divided into two general groups: heading, in which the leaves form a cabbage-like head; and cutting, in which the leaves are more loosely arranged. In each of these groups are forcing and out-door varieties. A third group, the cos or romaine varieties, which may be considered a subdivision of the cabbage group, consists of long, narrow-headed kinds, whose outer leaves must be tied above the head to properly blanch the inner ones. They are specially valued as summer lettuces, because of their ability to produce leaves of good flavor in spite of considerable heat.

Lettuce succeeds best in cool weather. It requires a rich open soil and clean cultivation; plenty of sunlight in the cool seasons and partial shade in the warm. The seed may be sowed in a hotbed where the plants may be either allowed to develop, or from which they may be transplanted to the garden, eight to twelve inches being allowed between them. Immense quantities of lettuce are forced in greenhouses during the winter, and from the trucking regions of the South, where the plants are grown with only sun heat in canvas-covered beds, the markets are supplied during the winter with thousands of carloads.

When grown under glass lettuce is sometimes attacked by so-called plant diseases—leaf-spot, rust, mildew, and drop or rot. These may be very largely if not wholly controlled by good management, especially with respect to ventilation, the temperature being kept lower than that which is favorable to the growth of the fungi. Sterilizing the soil with live steam at a temperature of about 200° F. for an hour or more is practised and believed by many large growers to destroy the spores. The operation is performed a day or so before planting.

Leucadia, lëf-kä-dë'ä, or **Leukas.** See SANTA MAURA and CAPE DUCATO.

Leucæmia, a disease of unknown origin, characterized by certain changes in the blood, with enlargement of the spleen and lymphatic glands. The disease may come on rapidly, with anæmia and loss of flesh and strength; usually the onset is insidious, the deterioration of the

LEUCIN—LEVASSEUR

general health or the swelling of the spleen or glands being first noticed. The changes in the blood consist in a decrease of the number of the red cells, diminution of the amount of haemoglobin in each cell, and great increase in the number of the leucocytes or lymphocytes. The most common form is that showing enlargement of the spleen and glands and peculiar changes in the bone-marrow; next in frequency is the form in which only the spleen and marrow are changed; and the form in which the glands alone are changed (the lymphatic) is considerably less common. Besides the increase in the number of the leucocytes, a form of the cell only found in the bone-marrow appears in the blood. The symptoms are due to the loss of nutrition of the tissues, to the anaemia, to the pressure of the enlarged spleen on the vital structures in the abdomen, and to the pressure of the enlarged glands. The glands most commonly enlarged are the chains along the neck, those in the axilla, the abdominal glands, the glands of the groin, and those of the thorax. They may be barely large enough to be felt or may form bunches in these parts that are plainly visible. Hemorrhages into the skin, eye, or internal organs may occur. The disease progresses for months or years with intervals of considerable improvement. No treatment can cure the disease, but benefit may be obtained from arsenic in large doses.

Leucin (Greek, "white"), a white substance, resembling cholesterol, first discovered by Proust in putrefying cheese, and afterward shown by Braconnot to be formed (together with other products) by the action of sulphuric acid upon animal matters. It is best prepared by the prolonged boiling of horn shavings in sulphuric acid, neutralizing with lime, precipitating excess of lime with oxalic acid, and then evaporating to crystallization. Leucin and tyrosin are thrown down together, but they may be separated by re-dissolving in water, and recrystallizing, the tyrosin then coming down first. Leucin has the chemical formula $C_6H_{10}O_4 \cdot NH_2$, and is known to the chemist as "amido-hexoic acid." (See AMIDE and HEXOIC ACID.) It may be sublimed, but if it be heated to 338° F. it melts, becoming simultaneously converted into amylamine, carbon dioxid, and ammonia. It is insoluble in ether, but soluble to some extent both in water and in alcohol. Leucin is said to occur in healthy calf's liver, and in certain other healthy tissues, such as the brain of the ox. It occurs also in certain of the products eliminated by the human skin, but its presence in the urine or in any of the internal organs of man is regarded as indicative of a serious pathological condition. Thus leucin is found in the liver in phosphorus poisoning and in acute yellow atrophy, and also in typhus fever and small-pox. In the healthy body leucin and tyrosin are probably converted into urea, and eliminated as such.

Leucippus, lü-sip'üs, Greek philosopher, flourished between the 4th and 5th centuries B.C. To him is attributed the first idea of the atomic system afterward perfected by his disciple Democritus. Kepler and Descartes were much indebted to the doctrines of these masters for the explanation of the planetary vortices.

Leucite, a native silicate of aluminum and potassium, having the formula $KAl(SiO_4)_2$, and

crystallizing in forms that are isometric at 900° F., but pseudo-isometric at ordinary temperatures. Its anomalous double refraction has been the subject of much study and discussion. The mineral is white or gray in color, and has a hardness of from 5.5 to 6, and a specific gravity of 2.50. It occurs more particularly in recent volcanic rocks, and Vesuvius is the best known locality for it. It is also found in considerable quantity in the Green River basin, Wyoming. Leucite may be converted into the mineral analcite by the action of a soda solution, and the inverse transformation of analcite into leucite is also possible.

Leucocytes. See BLOOD.

Leucomains. See METABOLISM.

Leuthen, loi'tén, or Lissa, Prussia, a village nine miles west of Breslau, which gives its name to the battle gained here by Frederick the Great, 5 Dec. 1757, over Prince Charles of Lorraine. The Austrians numbered about 90,000, and the Prussians 34,000. The Austrians lost 10,000 in killed and wounded, 12,000 were taken prisoners, besides considerable war munitions, and Silesia was regained. See SEVEN YEARS' WAR.

Leutze, loit'sé, Emanuel, American artist: b. Gmund, Würtemberg, 24 May 1816; d. Washington, D. C., 18 July 1868. He was brought to the United States in infancy and early displayed a talent for portrait painting. He studied at Düsseldorf under Lessing and lived abroad for many years after 1841. Among his works, which are largely historical, are: 'Columbus before the Council of Salamanca'; 'Columbus in Chains'; 'Columbus before the Queen'; 'Landing of the Norsemen in America'; 'Washington Crossing the Delaware,' perhaps his best known work; 'Washington at Princeton'; 'Lafayette in Prison at Olmütz Visited by his Relatives.' In 1860 he was employed by the United States government to make a large mural painting entitled 'Westward the Star of Empire takes its Way' on one of the staircases in the National Capitol.

Levant, le-vänt' ("sunrise," "orient"), in geology, a term applied by Henry Rogers to the fourth series of the Appalachian Palæozoic strata, called in New York the Medina group, and of equivalent age to the May Hill Sandstone or Upper Llandover of England. The name is given to signify metaphorically the sunrise period of the Palæozoic day. Its maximum thickness is above 2,000 feet, and most mountains of the Appalachian series are outcroppings of the Levant. There are few organic remains, chiefly marine shells and fucoids.

Geographically the word is a name applied to designate the coast of the Mediterranean immediately east of Italy, including the islands of the Ægean, Egypt, Asia Minor, and Syria.

Levasseur, Pierre Emile, pē-är ā-mél lé-vä-sér, French political economist and geographer: b. Paris 8 Dec. 1828. He was educated at the Collège Bourbon and the Ecole Normale, and after holding several important educational posts became in 1876 professor of geography at the Ecole Libre des Sciences in Paris. He has been especially prominent in regard to geographical study in French school and in addition to a series of geographies is author of

LEVEE — LEVER

‘Public Moneys among the Romans’ (1845); ‘The Gold Question’ (1858); ‘The Laboring Classes of France from Caesar’s Time to the Revolution’ (1859); the same continued to 1867 (2 vols.); ‘The French Population’ (1889–91), an important work; ‘France and her Colonies.’

Levee, lē-vē’ or lēvē’ (from the French word *lever*, to rise, and the time of rising). (1) In social usage, levee is a word used in high life or court language for the ceremonial visits which great personages receive in the morning, as it were at their rising. The levee is distinguished from the drawing-room, inasmuch as at the levee of a gentleman, gentlemen only appear, and at the levee of a lady, only ladies, while at the drawing-room, ladies and gentlemen both are admitted. The meaning is now more extended, and the term is applied chiefly to the stated occasions on which the king or queen of Great Britain publicly receives those subjects whom their rank entitles to the honor. On the first presentation of daughters of dukes, marquises, and earls, it is customary for the queen to kiss them on the cheek. The term is not used in the United States. (2) In hydraulic engineering, an embankment raised on the margin of a river to prevent inundation. That part of Louisiana which lies on the lower Mississippi was subject in a state of nature to the annual overflow of the river, by which immense damage was done to the land. To guard against these inundations, levees of earth have been thrown up for hundreds of miles along the river banks, to a height sometimes of 15 feet, with a breadth of 30 feet at the base. In front of New Orleans the levee is very broad, and serves as a wharf, steam-boats and other vessels being moored to it. Breaches sometimes occur in the levees, when the water rushes through and does great mischief; these breaches are called crevasses. See MISSISSIPPI LEVEE SYSTEM.

Level. (1) In mining, a horizontal gallery or passage. The workings at different depths are said to be at the different levels—the 50 or 60 fathoms level, and so on. A level which opens to the surface at the side of a valley is called a day level, and forms a means of natural drainage without pumping. A drowned or blind level is a drainage gallery which has the form of an inverted siphon. A dip-head level is the one which proceeds from the foot of the engine-shaft right and left, and from which the rooms diverge. (2) In surveying and engineering, an instrument for indicating a horizontal line or determining the position as to horizontality of an object or surface to which it is applied, and then determining the true level, or the difference of rise or fall between two or more places. There are numerous levels, varying in form, size, arrangement, or construction, according to the purpose for which each is intended; as, for instance, the carpenter’s, mason’s, gunner’s, or surveyor’s levels, the mercurial, water, and spirit levels, etc. All may be divided into three classes: (a) The simplest, such as the mason’s or carpenter’s level, in which the vertical line is determined by a plumb line, and the horizontal by a line perpendicular to it. (b) Those in which the horizontal line is determined by the surface of a fluid at rest; as in the water and mercurial levels. (c) Those in which the horizontal line is determined by a bubble of air

floating in a fluid contained in a glass tube; as a spirit level.

Levellers, the name of an ultra-reform party in Great Britain, which arose in the army of the Long Parliament about the year 1647, and was put down by Fairfax. They aimed at the establishment of an equality in titles and estates throughout the kingdom.

Leveling. See SURVEYING.

Leven, Loch, lōch lē’vn or lēv’n, Scotland, a lake in the county of Kinross, of oval shape, four miles long, two miles broad; greatest depth, 90 feet. It contains several islands, on one of which are the remains of the historic castle of Loch Leven, in which Mary Queen of Scots was confined after her separation from Bothwell and where she escaped shortly before the battle of Langside. The trout fishing of the lake is famous.

Lever, lē-vér, **Charles James**, Irish novelist: b. Dublin 31 Aug. 1806; d. Trieste, Austria, 1 June 1872. He was educated at Trinity College, Dublin, and after studying medicine, partly at Göttingen, he obtained the degree of Bachelor of Medicine from Trinity College in 1831. During the prevalence of cholera in 1832 he gained considerable reputation for his skill and devotion in the treatment of that disease. In March 1834 he contributed his first paper to the new ‘Dublin University Magazine,’ of which he was editor 1842–5. The first chapter of ‘Harry Lorrequer,’ a designation which he afterward made famous as his nom de plume, appeared in the February number for 1837. He removed to Florence in 1847, where he held a diplomatic position, was English consul at Spezzia in 1858 and at Trieste 1867–72. He published: ‘Harry Lorrequer’ (1837); ‘Charles O’Malley’ (1840); ‘Tom Burke of Ours’ (1844); ‘Jack Hinton’; ‘Arthur O’Leary’ (1844); ‘Roland Cashel’ (1850); ‘The Brambleights of Bishops Folly’ (1868); ‘Lord Kilgobbin’ (1872); etc. The rollicking character of the earlier of these was intensely national, and his later novels were more thoughtful and artistic.

Lever, lēv’ér or lēv’ér, one of the mechanical powers, a rod or beam of wood or metal by means of which a small force is enabled to balance or overcome a large one. The lever is supported at some point called the *fulcrum*, and it is movable about this point; the resistance to be overcome (called the *weight*), and the force which overcomes it (called the *power*), are applied at other parts of the lever. In order that the power and weight may balance each other, and so produce equilibrium, two conditions must be satisfied. In the first place, they must tend to rotate the lever round the fulcrum in opposite directions, that is, their moments or rotatory effects round the fulcrum must be of opposite sign; and secondly, the product of the number of units of force in the power into the number of units of length in the perpendicular from the fulcrum on its line of action must be equal to the corresponding product for the weight, or, in other words, the moments of the power and the weight about the fulcrum must be of equal magnitude. In the case of a straight lever with parallel forces, to which all other cases of the straight lever may be readily reduced, the equality of the moments may be tested by substituting the distance from the fulcrum

LEVERETT—LEVIS

along the lever to the point of application of the forces for the perpendicular distance above referred to. Levers are usually divided into three classes. The first includes those in which the fulcrum is between the power and the weight, the second those in which the weight is between the power and the fulcrum, and the third those in which the power is between the weight and the fulcrum.

Leverett, lēv'ér-ět, Frank, American geologist: b. Denmark, Iowa, 10 March 1859. He was educated at Denmark Academy and the Iowa Agricultural College. In 1886 he entered the United States Geological Survey; was assistant geologist 1890-1900; and since 1901 has been geologist. His special lines of investigation are glacial geology and water resources. He is a member of many scientific societies, and has published: 'Water Resources of Illinois' (1896); 'Water Resources of Indiana and Ohio' (1897); 'The Illinois Glacial Lobe' (1899); 'Glacial Deposits of the Erie and Ohio Basins' (1901); and various reports.

Leverett, Sir John, American colonial governor: b. England 1616; d. Boston, Mass., 16 March 1679. At 17 he emigrated to America with his father, and settled in Boston. He returned to England in 1644 to take part in the struggle between the parliament and the king, and as commander of a company of foot soldiers gained military distinction and the friendship of Cromwell. He subsequently resided some years at the court of the Protector, as agent of Massachusetts. On his return to America he held successively some of the most important civil and military offices in the gift of the colony, and finally in 1673 was elected governor. His administration is important in colonial history as the era of the war with King Philip, which his skill and energy were instrumental in conducting to a fortunate issue. Two years previous to his death he was knighted by Charles II. in acknowledgment of his services to the New England colonies during this contest.

Leverett, John, grandson of Sir John Leverett (q.v.): b. Boston 25 Aug. 1662; d. Cambridge 3 May 1724. He was an eminent lawyer and judge, speaker of the colonial legislature, and president of Harvard College from January 1707, until his death. He was a man of unusual attainments, and received the honor, then rarely bestowed upon colonial subjects, of membership in the Royal Society.

Leverrier, Urban Jean Joseph, ür-bān zhōn zhō-zéf lē-vā-rē-ā, French astronomer: b. Saint-Lô 11 March 1811; d. Paris 23 Sept. 1877. He was educated at the Collège Louis Le Grand and the Ecole Polytechnique, and devoting himself to astronomy, made observations which procured him admission to the Academy of Sciences in 1846. About this time he began investigating the perturbations of Uranus. He made calculations with the view of determining the mass and orbital elements of an unknown planet supposed to cause the disturbances, and was able to assign approximately the region where it might be looked for. John Couch Adams (q.v.), then a student at Cambridge, had been making investigations in the same track, and the honor of discovering Neptune (q.v.) is regarded as belonging equally to both. In 1854

Leverrier succeeded Arago as director of the Observatory of Paris, in which post, except an interval from 1870 to 1873, he remained until the end of his life.

Levi, lē'vī, one of the twelve patriarchs, a son of Jacob and Leah. The prince of the Shechemites having wronged his sister Dinah, he, with his brother Simeon, attacked their city and murdered all the males. Jacob reproaches them on his death-bed for this act of cruelty and foretells the dispersion of their descendants: "I will divide them in Jacob, and scatter them in Israel" (Gen. xliv. 7). Three sons went down with Levi to Egypt—Gershon, Kohath, and Merari (Gen. xlvi. 2). Moses and Aaron were of this tribe. See **LEVITES**.

Leviathan (Hebrew) is compounded of two words meaning a *great fish* and *fastened*; hence it probably means a huge fish covered with close scales. The Septuagint renders it *drakōn* (a dragon), and *kētos* (a whale). From the description given of it in the book of Job (xli.) it is usually, and probably correctly, considered to mean the crocodile, though in some places it has been interpreted the whale. See **TRISTRAM'S "NATURAL HISTORY OF THE BIBLE."**

Leviathan, The, a treatise on psychology, ethics and politics, by Thomas Hobbes, published in English in 1651, and in Latin in 1668.

Levin, Lewis Charles, American politician; b. Charleston, S. C., 10 Nov. 1808; d. Philadelphia 14 March 1860. Removing to Woodville, Miss., he became a school teacher and subsequently followed the practice of law in various states, settling permanently in Philadelphia in 1838. The temperance cause attracted him and he edited a temperance organ. Becoming known as speaker and writer, he formed the Native-American Party in 1843 and published *The Sun*, a daily paper, in its interests. As a representative of the party he was sent to Congress and served three terms (1845-51).

Levirate Marriage, among the Jews, the custom of a man's marrying the widow of a brother who died without issue. The same custom or law prevails in some parts of India.

Lévis, François Gaston, frāñ-swā gäs-tōñ lā-vē, DUC DE, French soldier in America: b. Château d'Anjac, Languedoc, 23 Aug. 1720; d. Languedoc 1787. He served in the French army in various campaigns, and in 1756 was ordered to Canada, where he became second in command to General Montcalm. For his services at the defense of Carillon in 1758 he was promoted major-general; and at Montmorenci in 1759 he repulsed the English under Wolfe. After Montcalm's death on the Plains of Abraham, Lévis took command of the French army, and during the winter of 1759-60 he maintained a vigorous struggle against great odds. He was victor at Sainte Foye in 1760, and might have gained Quebec if the French vessels had arrived at the opening of navigation in that spring. Lévis returned to France, where he continued in the military service; and was made a marshal in 1783.

Levis, lā'vē or lē'vīs, **Levis Town, or Point Levi, lē'vī,** Canada, the chief town of Levis County, Quebec, on the St. Lawrence River, opposite Quebec city, with which it has ferry communication. It is an important port with government docks; is the landing place for

transatlantic travelers, and the terminus of a branch of the Grand Trunk, and of the Levis and Kennebec railroads. It is strongly fortified, has several factories, stores, and lumber mills, and carries on a large trade by river and rail. Pop. (1901) 7,783.

Levites, lē'vīts, those of the tribe of Levi who were not priests. They were the ministers specially singled out for the service of the sanctuary, and, with the priests, formed the sacerdotal tribe. After the idolatry of the golden calf the Levites were the first to rally round Moses, and then the idea of a special consecration of 'an Israel within an Israel' developed itself, and the Levites thenceforth occupied a distinct position. They became guardians of the tabernacle, and no others approached it under penalty of death. From the first the Kohathites, as nearest of kin to the priests, had the highest offices assigned them. They bore the vessels of the sanctuary and the ark itself. A permanent arrangement was made for their maintenance. They were to receive the tithes of the produce of the land, and in their turn to offer a tithe to the priests. When the tabernacle should have a permanent place, the whole tribe was to be assigned forty-eight cities, six of which were to be cities of refuge. The Levites were moreover to preserve, transcribe and interpret the law, and to read it every seventh year at the Feast of Tabernacles. They were not included in the general census of the people, but in a separate census (I. Chron. xxiii. 3); their number is given at 38,000. Their position was much changed by the revolt of the ten tribes, and after the captivity, in the movement under Ezra, not more than 38 could be brought together. The purity of their blood was stringently guarded both by Ezra and Nehemiah. After the destruction of the temple in the dispersion, they disappeared from history, being merged in the crowd of captives scattered over the Roman world.

Levit'icus, the third book of the Pentateuch, or five books of Moses. By the later Jews it was called the 'Law of the Priests,' and sometimes the 'Law of Offerings.' It consists of seven sections, but it may be generally described as containing the laws and ordinances relating to Levites, priests and sacrifices. The regulations respecting the sacrifices are classed in three groups, each consisting of ten directions. After this section comes a historical section, giving particulars of the consecration of Aaron and his sons, his offering for himself and the people, and the episode of Nadab and Abihu. Then follow laws concerning purity and impurity; laws relating to the position of Israel as markedly distinct from the nations around; a section of laws concerning the priests, holidays, festivals, etc.; a section of promises and threats; and a final section or appendix on vows. Some critics regard Leviticus as forming part of the Priestly Code, and assert that it was post-exilic and belongs to the latest portions of the Pentateuch.

Lev'ulose, a sugar isomeric with dextrose (q.v.) and always occurring with it in honey, in many fruits, and in other sacchariferous vegetable organs, but distinguished by turning the plane of polarization to the left. See also SUGAR.

Lévy, Emile, ā-mēl lä-vē, French painter: b. Paris 20 Aug. 1826; d. Paris 4 April 1900. He studied at the Ecole des Beaux Arts and was also a pupil of Picot and De Pujol; he won the Grand Prix de Rome in 1854. In 1878 he was awarded a first class medal for a picture he exhibited in the Salon. He had received the cross of the Legion of Honor in 1868, and was much valued as a portrait painter. He was also successful in pastel. Among his works are: 'The Death of Orpheus' (1866) now in the Luxembourg; 'Supper of the Martyrs' (1859); 'The Elements' in the Louvre; and 'Presentation of the Virgin' in the Church de la Trinité, etc.

Levy, lē'vī, Louis Edward, American photo-chemist and inventor: b. at Stenowitz, Bohemia, 12 Oct. 1846. Coming to the United States in boyhood he received his early education at the Detroit public schools. He gave special attention to mathematics and astronomy at the University of Michigan (1866) and to practical optics in Detroit (1861-70). He was connected with the U. S. Lake Survey (1866), made researches in microscopic photography (1867-70) and invented a process in photochemical engraving (1875) called the 'Levy-type.' He received (1896) with his brother Max, a medal for invention of 'Levy line screen,' and (1900) a gold medal for Levy 'acid blast,' both from Franklin Institute, Philadelphia, and a medal and diploma from the World's Columbian Exposition (1893) for original discoveries. He has published and edited in Philadelphia *The Evening Herald* (1887-90); 'The Mercury' (1887-91); and has edited 'The Jewish Year' (1895); 'The Russian Jewish Refugees in America' (1895); 'Business, Money and Credit' (1896). He was elected vice-president of Inventors' Association at Paris in September 1900.

Levy, Uriah Phillips, American naval officer: b. Philadelphia 22 April 1792; d. New York 22 March 1862. Sailing as a cabin boy before his 11th year, he was apprenticed as a sailor in 1804, and before he was 20 had passed through every grade and become master. On 23 Oct. 1812, he was commissioned sailing-master in the navy, serving until June 1813 on the ship Alert and then on the brig Argus. He was placed in command of one of the prizes which the Argus secured, but it was subsequently recaptured and he, with his crew, was imprisoned in England for 16 months. In March 1817, he was appointed lieutenant. Personal antagonism, in which religious prejudice played an important part, subjected him to nearly forty years' struggle, in the course of which he fought a duel, killed his opponent, was court-martialed six times, and finally dropped from the list as captain. He was finally restored to that rank in 1855 and later became commodore. His staunch American spirit was proved by his admiration for Thomas Jefferson, whose home at Monticello he purchased.

Levy, lev'i, (1) a term used in Europe for the compulsory raising of a body of troops from any specified class in the community for purposes of general defense or offense when the existing military forces are insufficient to meet the necessities of the case. When a country is in danger of instant invasion a *levée en masse* is sometimes made—that is, every

LEWIS—LEWIS AND CLARK EXPEDITION

elected lieutenant-governor of the State on the ticket with G. C. Walker. In 1869 he was also elected as a Republican to the United States Senate, where he served from 24 Jan. 1870 to 3 March 1875. He was appointed (1877) by President Hayes United States marshal for the western district of Virginia, but afterward resigned the post.

Lewis, Matthew Gregory, called "Monk" Lewis, English author: b. London 9 July 1775; d. at sea on the way from Jamaica to England 14 May 1818. He was educated at Oxford, in 1794 became a member of the British embassy at The Hague, and in 1795 published '*Ambrosia, or the Monk*' (whence his sobriquet), which had a great success at the time. In 1796–1802 he represented Hindon, Wiltshire, in the Commons. Of his various dramatic works the best-known is '*The Castle Spectre*', first presented in 1798, and abounding in storms and other melodrama. He visited, in 1815–6 and 1817–8, his property in the West Indies, to provide for the suitable treatment of his negro slaves; and published the '*Journal of a West Indian Proprietor*', which is interesting as a description of the condition of the negro in Jamaica of that time. His writings had considerable influence on the early poetry of Walter Scott, for whose translation of '*Götz von Berlichingen*' he obtained the publication in 1799.

Lewis, Meriwether, American explorer: b. near Charlottesville, Va., 18 Aug. 1774; d. near Nashville, Tenn., 8 Oct. 1809. He enlisted in the troops called out for suppression of the "Whiskey Rebellion" in western Pennsylvania in 1794, entered the regular service in 1795 as lieutenant of the line, in 1797 was promoted captain, in 1801–3 was private secretary to Jefferson, and in the latter year was appointed commander of an expedition to cross the continent, with Capt. William Clark (q.v.) as second in command. On 5 July 1803 he left Washington for Pittsburgh, Pa., where the expedition was equipped; but he did not begin to ascend the Missouri until the ice had broken in the spring of 1804. Then he proceeded up the river to its sources, crossed to the Rocky Mountains, reached the headwaters of the Columbia River, floated down that river to the Pacific, and explored a large part of the Oregon region. He had covered in all more than 4,000 miles from the junction of the Missouri with the Mississippi. Having wintered in an entrenched camp on the south bank of the Columbia, he started eastward 23 March 1806, and arrived at Washington 14 Feb. 1807. He received a grant of land and was appointed governor of Louisiana, where he found much confusion, and where he was successful in restoring order. He was a bold explorer, and familiar with Indian matters. Consult memoir by Biddle and Allen (new ed. 1843), and Lighton, '*Lewis and Clark*' (1901; Riverside biography series). See also LEWIS AND CLARK EXPEDITION.

Lewis, Morgan, American statesman: b. New York 16 Oct. 1754; d. there 7 April 1844. He was graduated from the College of New Jersey in 1773, studied law, in 1774 entered the Continental army, was commissioned major in the 2d New York, later became chief-of-staff to Gates with colonel's rank, and quartermaster-general of the northern army. He commanded at Crown Point; and after the war entered legal

practice in New York. Elected to the assembly, he also became judge of the court of common pleas, attorney-general of New York (1791), judge of the supreme court (1792), chief justice of the court (1793), and governor (1804–7). In 1810 he was elected to the State senate, in 1812 became quartermaster-general of the armies of the United States, in 1813 was promoted major-general, and was in command at Sackett's Harbor and French Creek. He was president of the New York Historical Society, and president-general of the Cincinnati.

Lewis, Tayler, American author and educator: b. Northumberland, N. Y., 27 March 1802; d. Schenectady, N. Y., 11 May 1877. He was graduated at Union College in 1820; studied law in Albany, and practised at Fort Miller, but soon gave nearly all his time to the study of classical literature. In 1838 he was appointed professor of Greek at the University of New York, and in 1849 accepted the same professorship at Union College. He attained distinction as a philologist and in Christian apologetics. Besides contributing largely to periodicals, he published the following works: '*The Nature and Ground of Punishment*' (1844); '*Plato contra Atheos*' (1845); '*The Six Days of Creation*' (1855); '*The Bible and Science*' (1856); '*The Divine Human in the Scriptures*' (1860); '*State Rights, a Photograph from the Ruins of Ancient Greece*' (1864); and '*The People of Africa, Their Character, Condition, and Future Prospects*', with E. W. Blyden and Timothy Dwight (1871). He was a member of the Bible Revision Committee.

Lewis, William Draper, American lawyer: b. Philadelphia 27 April 1807. He was graduated at Haverford College in 1828, and at the University of Pennsylvania in 1831. In the latter year he was instructor in legal historical institutions in the Wharton School, University of Pennsylvania; from 1830 to 1836 was lecturer on economics at Haverford, and has edited the '*American Law Register*'. He has written: '*Federal Power over Commerce and Its Effect on State Action*' (1891); '*Our Sheep and the Tariff*' (1891); and many periodical articles on legal, historical, and economical subjects. Among the works which he has edited are '*Wharton's Criminal Law*' (1895); '*Lewis' Edition of Greenleaf's Evidence*' (1896); '*Lewis' Edition of Blackstone's Commentaries*' (1897); '*Digest of Decisions and Encyclopedia of Pennsylvania Laws*'; etc.

Lewis, or Lewis-with-Harris, Scotland, the largest of the Hebrides, separated from the mainland by the Minch, a sea 30 to 35 miles wide. The northern larger portion, Lewis, is in Ross-shire, and is separated by a narrow neck from the southern portion, Harris, which belongs to Inverness-shire. The island is 52 miles long, varies in breadth from 5 to 30 miles, and has a diversified surface, which attains an elevation of over 2,700 feet. Capital, Stornoway. Pop. of island (1901) 32,160.

Lewis and Clark Expedition, The, in American history, a celebrated expedition to the northwestern part of the United States in 1803, under the command of Captain Meriwether Lewis of Virginia, and Captain William Clark, the results of which gave a more definite idea of our natural resources in this hitherto unexplored region than had ever been known. Recognizing

LEWIS FORK—LEWISTOWN

the importance of a thorough and accurate knowledge of the vast extent of country acquired by the United States with their independence, Thomas Jefferson, while minister to France suggested to the traveler, Ledyard, an exploration of western America. Nothing came of it, however. In 1792 he made a similar proposition to the American Philosophical Society (q.v.), and Michaux, the celebrated traveler and botanist, proceeded as far as Kentucky, when he was recalled by the French minister. In January 1803, in a confidential message to the Congress, President Jefferson recommended an appropriation for this purpose. It was granted and he appointed Lewis, who had been his private secretary nearly two years, to the command of the expedition along with Clark. They made an adventuresome journey with a small party of soldiers, guides and Indians to the unknown northwest. Their travels extended to the Pacific Ocean on the west and the Columbia river on the north. The expedition was highly successful and reports of the greatest value were received by the government at intervals covering a period of three years. Afterward a highly interesting account of the expedition and its discoveries was published. This volume for 100 years has been one of the most valued of American historical works and as late as 1903 no less than three reprints of the book were published. Lewis was a man of great energy and perseverance, and upon his return was appointed governor of the Louisiana Territory.

Lewis Fork. See SNAKE RIVER.

Lewisburg, lü's-berg, Pa., borough, county-seat of Union County; on the Susquehanna River, and on the Philadelphia & R. and the Pennsylvania R.R.'s; about 50 miles north of Harrisburgh. It is on the border of the great anthracite coal fields, and in a fertile agricultural valley. Its chief manufactures are flour, lumber, furniture, shirts, woolen goods, machine shop products, and acetylene gas. Its trade is chiefly in its manufactured products and in grain and vegetables. It is the seat of Bucknell University, opened in 1846 under the auspices of the Baptists. Pop. (1900) 3,457.

Lewisburg, Battle of. On 21 May 1862 Gen. Heth, with a Confederate force of three regiments of infantry, a battalion of dismounted men, a regiment of cavalry and three batteries, aggregating about 2,200 men, marched from Salt Sulphur Springs, Va., on Lewisburg, 24 miles distant, to surprise Col. Geo. Crook who was encamped at that place with about 1,500 men. Heth marched through Union, crossed Greenbrier River, driving in Crook's pickets, and at 5 A.M. of the 23d formed line on a hill east of the town, Crook's camp being on the west side. Crook threw out a well supported skirmish line, which soon engaged Heth's advance; Heth at first had some success, but was gradually forced back; Crook charged his main line; a panic seized Heth's troops, and they fled from the field in disorder, retreating across the Greenbrier and burning the bridge behind them. Heth left on the field 38 dead and 66 wounded, four guns, and over 200 stand of small arms. Over 100 of his unwounded men were captured. Crook's loss was 13 killed, 53 wounded, and 7 missing. Consult: 'Official Records,' Vol. XII.;

The Century Company's 'Battles and Leaders of the Civil War,' Vol. II.

E. A. CARMAN.

Lewiston, lü's-tön, Maine, city, in Androscoggin County; on the Androscoggin River, and on the Maine C., and the Grand T. R.R.'s; about 28 miles southwest of Augusta, and 32 miles north of Portland. It was settled in the early part of the 17th century but was founded as a district in 1770, and called "Plantation of Lewiston" until 1795, when it was incorporated as a town, and was chartered as a city in 1861. Lewiston is located in an agricultural region, but the extensive water-power has contributed toward making it a manufacturing city. The river here has a fall of about 50 feet, and the power is utilized by means of a distributing dam and canal. Bridges connect the city with Auburn on the opposite side of the river. The chief manufactures are cotton and woolen goods, foundry products, machinery for cotton and woolen mills, engines, boilers, brick, lumber, belting, boots and shoes. The dye works and bleacheries are quite extensive. Some of the principal buildings are the Carnegie library, in which are the Manufacturers' and Mechanics' library, having over 10,000 volumes; a city hall, Healy Asylum (R. C.), Hospital of Our Lady of Lourdes (R. C.), two convents, several fine churches and schools. It is the seat of the Bates College (q.v.) which includes the Cobb Divinity School. Pop. (1890) 21,701; (1900) 23,761.

Lewiston, N. Y., village, in Niagara County; on the Niagara River, and on the New York Central & H. R. railroad; seven miles north of Niagara Falls, and about 25 miles north of Buffalo. It has communication by steamer with a large number of lake ports. The place where Lewiston now stands was the site of an Indian village. In 1720 the French took possession of the place, but abandoned it in a few years, when it was again occupied by the Indians. Joseph Brant's home was in this vicinity. On 14 Sept. 1763 occurred the Indian massacre at Bloody Run, a place near Lewiston. The first white settlement was made about 1800, and in 1818 the town was incorporated, and in 1843 the village. On 19 Dec. 1813 Lewiston was burned by the English and Indians. The place is now a favorite summer resort. Pop. (1900) 697. Consult: Pool, 'Landmarks of Niagara County.'

Lewistown, Ill., city, county-seat of Fulton County; on the Chicago, B. & Q. and the Fulton County Narrow Gauge R.R.'s; about 50 miles northwest of Springfield. It is situated in an agricultural region and is the trade centre of a large part of the county. Its chief manufactures are carriages and wagons, flour, lumber, brick, tile, furniture, and dairy products. Livestock and farm products are shipped from Lewistown to the large markets. Pop. (1900) 2,504.

Lewistown, Pa., borough, county-seat of Mifflin County; on the Juniata River, and on the Pennsylvania railroad; about 60 miles northwest of Harrisburg. It is situated in a fertile agricultural region in which are valuable mineral deposits. Lewistown is a trade centre for an extensive farming section; but it is also a manufacturing borough. The chief manufactures are steel, iron, flour, leather, lumber, foundry and

LEXICOGRAPHY — LEXINGTON

machine-shop products, hydrants, and pumps. Lewistown and vicinity are now favorite summer resorts. Pop. (1900) 4,451.

Lexicography. See DICTIONARY.

Lexington, lēk'sīng-tōn, Ky., city, county-seat of Fayette County; on the Lexington & E., the Southern, the Chesapeake & O., the Kentucky & I. B., and the Louisville & N. R.R.'s; about 82 miles south of Cincinnati, and about 22 miles southeast of Frankfort, the capital of the State. The first settlement was claimed by a party of hunters, who, in 1775, camped at this place and named it Lexington in honor of the battle of Lexington. They built a log cabin on the site so as to leave a proof of their ownership. Four years later Robert Patterson, one of the hunting party, made here a permanent settlement. Three years afterward the town was incorporated by the legislature of Virginia, as this section was then a part of Virginia. In 1792, when Kentucky became independent of Virginia, Lexington was made the capital of Kentucky, and the first Kentucky legislature met in this city. The city was granted a charter in 1832. Lexington is located in a fertile agricultural country, the famous "blue-grass" region. Its chief manufactures are Bourbon whisky, harnesses, saddlery, flour, canned goods, lumber, carriages and wagons. Some of the important institutions are Kentucky University (Christian), Sayre Female Institute, Hamilton and McClelland Female Colleges, Saint Catharine's Academy (Roman Catholic), State Agricultural and Mechanical College, and the Kentucky Reform School. It has the State Asylum for the Insane, Saint Joseph's Hospital (Roman Catholic), Colored Industrial Home, and a Protestant infirmary. It has an excellent public library. The race tracks, the stock farms in the vicinity, the parks, all have made Lexington well known in connection with industries and amusements. Henry Clay made this city his home from 1797 until his death. Pop. (1890) 21,567; (1900) 26,369.

Lexington, Mass., town, in Middlesex County; on the Boston & M. railroad; about 12 miles northwest of Boston. The town contains the villages of Lexington, East Lexington, and North Lexington. Lexington was settled in 1642, was long known as "Cambridge Farms," and was incorporated as a town in 1713. It was the scene of the first conflict between the colonists and the British troops in the Revolutionary War, on 18 April 1775. The British obtained the advantage and destroyed the stores of the colonists, but lost in the action 273 men killed and wounded. Lexington is situated in an agricultural region, and its industries are connected chiefly with the products of the farms and the trade necessary for supplying local wants. It has important leather-binding works. It contains many points of interest, some of which are the first battleground of the Revolutionary War, the monument commemorative of this battle; the Monroe Tavern, built in 1695, which was Earl Percy's headquarters; the old Belfry clubhouse; and the Hancock-Clarke house (1698), where Samuel Adams and Hancock lodged the night before the battle. The last mentioned building is now used as a museum for Revolutionary and early settlement relics. A number of monuments in honor of the men and events

which made Lexington famous adorn the city. It contains the Cary Library with nearly 25,000 volumes; a fine high school, the Hancock and Adams grammar schools, a town hall, and a number of fine churches and elegant residences. The old burying ground, visited annually by hundreds of people, is mute witness of the noble people who have lived in this town. Pop. (1900) 3,831.

Lexington, Mo., city, county-seat of Lafayette County; on the Missouri River, and on the Missouri P. and the Atchison, T. & S. Fe R.R.'s; about 63 miles southeast of Saint Joseph and 39 miles east of Kansas City. The first permanent settlement was in 1825, and it was incorporated in 1830. Lexington was the scene of a siege in 1861, when a Confederate force of 18,000 under Gen. Sterling Price, attacked the city, which was defended by a Federal force of 3,000 men under Col. James Mulligan. The Federals surrendered on 20 Sept. 1861, but Price left the place a few days later, and put on guard a small force. On 16 October, a Federal force of 230 men under Major J. White entered the city, released the Union prisoners and took the Confederates captive. The city is in the midst of a fertile agricultural region, in which hemp is cultivated extensively. Coal is mined in the vicinity of the city. Lexington is the seat of the Central Female College, the Baptist Female College, and the Wentworth Military Academy. Pop. (1900) 4,190.

Lexington, Va., town, county-seat of Rockbridge County; on the north fork of the James River, and on the Baltimore & O. and the Chesapeake & O. R.R.'s; about 110 miles west by north from Richmond, and 44 miles northwest of Lynchburg. It is in a rich farming valley west of the Blue Ridge. Valuable deposits of sulphur ore are in the vicinity. The chief manufactures are dairy products, agricultural implements, flour, and lumber. The city owns and operates the waterworks. The water is brought some distance from springs in the mountains. Lexington is the seat of the Virginia Military Institute, opened in 1839, and the Washington and Lee University (q.v.). Generals Jackson and Lee are buried here, and statues have been erected in their memory. The mineral springs in the vicinity are becoming popular resorts; the Natural Bridge (q.v.) one of the natural curiosities of America, is about 15 miles south, separated from Lexington by low mountains or hills. Pop. (1900) 3,203.

Lexington, Siege of. After the battle of Wilson's Creek (q.v.), Mo., 10 Aug. 1861, Gen. Sterling Price, abandoned by McCulloch and his troops, appealed to the secessionists of Missouri to fill his depleted ranks; and about the middle of August he moved northward toward the Missouri River, skirmished with a force under Gen. J. H. Lane, 7 September, at Dry Wood Creek, drove Lane out of the State, and followed as far as Fort Scott, which had been abandoned. On the 10th he was at Rose Hill, from where he marched for Warrensburg, which was reached on the 11th, Peabody's 13th Missouri at that place retreating to Lexington. When Fremont, at St. Louis, heard of Price's northward movement, he ordered to Lexington a force which, when Price arrived at Warrensburg, numbered 2,800 men, with seven 6-pounder

LEXOW — LEYDEN

guns, under command of Col. James A. Mulligan, 23d Illinois. Mulligan took position and threw up intrenchments on College Hill, a bluff 200 feet above low-water mark, northeast of the city, overlooking it and the Missouri, and on which was a substantial brick building erected for a college. Immediately in front of the college was the first line of works, outside of which was a broad ditch, and beyond were "confusion" pits. On the morning of the 11th Price marched from Warrensburg toward Lexington, and that night, after a march of 30 miles, halted three miles from the city, where he rested until dawn, when he drove in Mulligan's pickets, and from four different points opened a cannonade upon the hastily constructed works around the college. After several sharp encounters the Confederates captured some outworks and drove Mulligan's men behind the main line. At the end of the day Price withdrew to the fair ground, two miles away, to await reinforcements and ammunition. Mulligan, looking for reinforcements, strengthened his position and prepared for a siege. Price was anxious because he knew of the approach of Union troops to relieve Lexington; but being reinforced to 25,000 men, and his ammunition coming up, he again moved on the city on the 18th, took possession, closed in upon Mulligan, and began a siege. Rains' and Parsons' divisions occupied strong positions on the east, northeast, and southwest of the works; Rives' division, supported by McBride's command and a part of Harris', moved along the river bank to a point immediately beneath Mulligan's works; fire was opened upon the Confederates from a dwelling on the bluff, 125 yards from the works; upon which the Confederates charged and took the house, and also the bluff immediately north of it. A gallant counter-charge by Capt. Gleason, with 80 men of the 23d Illinois, retook the house, but it was soon regained, and the adjoining heights fortified. Firing continued all day of the 19th; water gave out, but Mulligan encouraged his men to hold on until help arrived. On the morning of the 20th Price caused to be taken to the river heights a number of hemp-bales, with which movable breastworks were constructed. These were rolled forward; under cover of them the Confederates moved to within ten rods of the works; and at 2 p.m., after over two days' continuous fighting, Mulligan's men being without water or rations, and short of ammunition, a white flag was displayed, and Price ordered a cessation of firing. Mulligan had lost 42 killed and 108 wounded, and surrendered 1,624 men, 7 guns, many horses, and a large amount of stores. Price reported a loss of 25 killed and 72 wounded. Price remained at Lexington until 30 September, when, pressed by the Union advance from Jefferson City, he abandoned the place and retreated toward Arkansas, leaving a guard of 500 men with the prisoners taken. On 16 October a squadron of cavalry under Maj. F. J. White surprised the party, captured 70, and released the prisoners. Consult: "Official Records," Vol. III.; The Century Company's "Battles and Leaders of the Civil War," Vol. I.

E. A. CARMAN.

Lexow, lëk'sow, Clarence, American lawyer and politician: b. Brooklyn, N. Y., 16 Sept.

1852. He studied abroad and at the Columbia Law School, graduating from the latter in 1872. He was admitted to the bar and established practice in New York city, receiving a large German-American patronage, and engaging in many important litigations. In 1882 he became a resident of Nyack, and was active in the Republican party there. In 1890 he was an unsuccessful nominee for Congress, but lowered the usual Democratic majority. In 1893 he was elected to the State Senate where he served till 1898. Here he at once became a leader, was chairman of the committee on internal affairs, and introduced the bi-partisan police bill calling for an investigation of the New York city police. This led to the appointment of the so-called "Lexow Committee," of which he was head; the investigations of this committee brought to light the system of protection of vice by the police in New York, and were the direct cause of the reform campaign and the election of Mayor Strong. Lexow was also the introducer of the bill creating the city of Greater New York, was chairman of the joint legislative committee for the investigation of trusts and unlawful combinations, of the committee on primary elections reform and of the judiciary committee. In 1896 he was chairman of the committee on resolutions at the Republican State convention, and introduced the gold standard plank in the platform; in 1900 he was a presidential elector. He is author of reports on "Municipal Government" and on "Trusts and Unlawful Combinations".

Leyden, li'dén, or Leiden, Netherlands, an important town in the province of South Holland, 22 miles by rail southwest of Amsterdam, on both sides of the Old Rhine, which flows through the town by several branches. The neighborhood is marked by wind-mills, country-seats, pleasure-grounds, gardens, and fertile meadows, and street railroads connect with the bathing resort of Katwyk, 5 miles to the northwest on the North Sea. The streets are straight, broad, and clean; Broad Street (*Breede-straat*) being esteemed one of the finest in Europe. In it is situated the town-hall (*Stadhuis*), originally founded toward the end of the 16th century, a picturesque building, with 30 windows in a line in front, a tall spire, and three highly ornamented projecting gables. In the council-chamber are the painting of the "Last Judgment," by Lucas van Leyden, and several good historical portraits; in part of the lower floor is situated the meat-market. None of the churches are remarkable; the Reformed Church of St. Peter contains monuments to Boerhaave, Spanheim, Scaliger, etc. The most important educational institution is the university, formerly one of the most famed in Europe, and still in excellent repute. It is attended on the average by about 800 students, nearly one half studying law. Connected with the university are a well-laid-out botanic garden, an observatory, a library, with numerous manuscripts, an anatomical theatre and museum of comparative anatomy, one of the richest collections of natural history in existence, cabinet of coins, museum of antiquities, and a rich Japanese museum. Leyden was noted for its cloth manufactures, which after 1670 declined, but have revived in recent years, now employing about 1,500 operatives. There are also various other branches of manufacture, and the former great

LEYDEN JAR—LHASA

trade in books, carried on in the latter part of the 17th and during the greater part of the 18th century, and rendered world-renowned by the Elzevirs, is represented by several printing offices. There is an extensive trade in agricultural produce, especially cheese and butter.

The most memorable event in the history of Leyden is the successful siege it maintained against the Spaniards in 1573-4 until relieved by the action of the Prince of Orange in breaking down the dikes. Leyden is the birthplace of John of Leyden, the founder of the Anabaptists; Camper, Muschenbroek, the brothers Gerard and Isaac Vossius, Gronovius, Rembrandt, Luke of Leyden, the brothers Van der Velde, Gerard Douw, etc. Pop. (1900) 54,421.

Leyden Jar. See ELECTRICITY.

Leys, Henri Jean Auguste, öñ-ré zhōñ ð-güst lis, or là, Belgian painter: b. Antwerp 18 Feb. 1815; d. there 25 Aug. 1869. He worked from 1829 to 1832 in the studio of his brother-in-law, Ferdinand de Braekeleer, and in 1833 exhibited in Brussels, 'Fight Between a French Grenadier and a Cossack.' He, attracted still further attention by his picture 'Fight of Burgundian and Flemish Soldiers.' His style changed after his visit to Paris 1835; during which he confined himself to a study of the French Romantic school. Yet while the modern manner is discernible in his works, he shows himself also under the influence of Van Dyck and Rembrandt in such pictures as: 'Flemish Wedding'; 'A Painter's Studio'; 'A Family Party in Brittany'; 'Burgomaster Six at Rubens' House'; etc. In 1839 he still further modified his manner after traveling in Holland and familiarizing himself with the Dutch genre painters. It was certainly under their inspiration that he painted such pictures as 'A Family Party' (1845); 'Divine Services in Holland' (1850); etc. After completing his travels in Holland he still further changed his style and painted in the bizarre style of Quentin Matsys, whose naïveté and uncouthness he also reproduced. In 1863 he received a commission to decorate with frescoes the town hall of Antwerp, and this he fulfilled by producing a fine series of scenes from the history of the city. He was also an etcher, lithographer and wood engraver of acknowledged skill.

Leyte, lá'tā, Philippines, a province consisting of the island of Leyte and 40 dependent islands; area of Leyte 3,872 square miles; area of dependent islands 342 square miles; total 4,214 square miles. Leyte lies southeast of Luzon, southwest of Samar, from which it is separated by the narrow strait of San Juanico, and northwest of Mindanao; its extreme length from northwest to southeast is 121 miles. The two most important dependent islands are Biliran, area 144 square miles; and Panaón, area 76 square miles. They are both mountainous; Biliran is noted for its sulphur springs; Panaón is well populated and has some gold deposits. The interior of the island of Leyte is mountainous, there being a number of extinct volcanoes, and the island is crossed by a number of large rivers; the coast line is irregular, indented by a number of bays, some of which afford excellent harbors, among the best in the Philippines. There are numerous roads on the east coast, and the west coast is also paralleled by roads and trails for almost its entire length;

the rivers furnish good inland transportation. The province is one of the best cultivated in the archipelago; the most important product is hemp and many of the plantations being under cultivation for almost 50 years require little work, the crop being abundant and of excellent quality; other products are rice for home use, chocolate, sugar, coffee, and corn. The mineral products include sulphur, gold, iron, lead, and silver; of these the most important is sulphur, which supplied the gunpowder works at Manila under Spanish rule. There are also valuable forests; the yield of dammar, the brea or pitch of the Spaniards, is the most important in the Philippines. The largest industries are the manufacture of abaca and the cabonegro or black boat cables from the hemp, and the extracting of cocoanut oil. There are also ship-building yards at Tacloban, at which good sized schooners are often built, and weaving of fine fabrics by the women. Civil government was established in April 1901; the people proved generally favorably inclined to the new regime, and there was renewed activity in every line of industry; before December of that year the United States troops were withdrawn from a number of the towns, which had been garrisoned, and they were protected entirely by the native police. Pop. 270,500, mostly Visayan.

Lhasa, lhă'să or Lassa, lăs'să, Tibet, the capital of the country, and the "Rome" or "Mecca" of Buddhism, its name signifying the "Place of God," is picturesquely situated in a valley plain surrounded by mountains rising from the Ki-chu, a left affluent of the Sango or Upper Brahmaputra, about 280 miles in a direct line northeast of Darjiling. Access being exclusively forbidden to Europeans, three only having visited it during the 19th century, the place has a mysterious celebrity, which has been enhanced by unsuccessful western attempts to reach it. The most recent information has been obtained from native Hindu pilgrims and explorers in the employ of the British Government. Broad roads lined by luxurious gardens lead past the well-built houses of the suburbs to the closely guarded gates of the walled city, which is dominated by the imposing Potala hill-palace, and other hill-top edifices. The principal streets of the city are wide, regular, and clean, lined with well-stocked stores and houses of two and three stories; but the side streets and lower parts of the town are very dirty and daily crowded by importunate beggars. The houses are built of stone, brick, or earth, terraced at the summit, and uniformly whitened externally, the windows and door-frames being painted with the sacred or *lamanesque* colors, red and yellow. Internally, however, they are exceedingly dirty and comfortless. The public edifices worthy of notice are connected with Buddhist monasteries. In the heart of the city is the convent of Moru, with a large printing establishment, from which numerous religious works are issued; and on the outskirts, toward the cardinal points, are four other large monasteries—Praebung on the west, Sera on the north, Khaldan on the east, and Samie on the south or southeast side. All these have several thousand inmates, being greatly resorted to from China, Turkestan, Nepal, etc., as schools of philosophy and Buddhism. About 1½ miles northwest from the city, and connected with it by two avenues of trees, is the Potala,

L'HÔPITAL—LI HUNG CHANG

Bottala, or Buddha-la, the residence of the Dalai or Talé (Grand) Lama, the ecclesiastical sovereign of Tibet, and supreme pontiff of the vast regions forming central, eastern, and southeastern Asia. A triple-peaked hill here rises abruptly out of the plain to the height of 367 feet; it is covered with convents and cells of monks, and in the centre is the palace of the Dalai Lama, a fine edifice, four stories in height, with a vast number of apartments and a large dome, which, like the columns of the peristyle surrounding the structure, is covered with gilding. The interior is full of idols, treasure, and works of art. Lhasa is the principal emporium of Tibet, and a rendezvous of people from all parts of Asia; silk stuffs, tea and other articles being here exchanged for Tibetan, Indian, and European goods. British troops under Col. Young-husband were ordered into Tibet in the autumn of 1903, apparently to occupy Lhasa, and thus control the entire Buddhist population of Asia, in behalf of British interests. Pop. of city estimated at 15,000, but in addition there are a large number of Buddhist lamas or priests, and students in the monasteries.

L'Hôpital, Guillaume François Antoine, gē-yōm frān-swā āñ-twāñ lō-pē-tāl, MARQUIS DE ST. MESME, French mathematician: b. Paris 1661; d. 2 Feb. 1704. He devoted himself exclusively to the study of mathematics, having had Jean Bernouilli for a short time to give him instructions in the differential and integral calculus, and at the age of 32 distinguished himself by solving problems proposed to the lovers of mathematics by Jacques Bernouilli; and 1693 was admitted an honorary member of the Academy of Sciences at Paris. From that period he published, in the French and foreign journals, solutions of difficult questions, and other mathematical communications. Such was his reputation that Huygens, profound as was his acquaintance with science, applied to L'Hôpital for information relative to the nature of the differential calculus. This led to the publication of his 'Analyse des Infiniment Petits' (1696), the first French work on the subject, of which a new edition was published by Lefevre (1781). Besides the work mentioned he was the author of 'Les Sections Coniques, les Lieux Géométriques, la Construction des Equations' (1707); and 'Une Théorie des Courbes Mécaniques.'

L'Hôpital, Michel de, mē-shēl dē, French statesman: b. Aigueperse, Puy de Dôme, France, about 1504; d. Chateau Bellebat, near Etampes, France, 15 March 1573. He studied law in Italy, and returning to France was president of the court of accounts in 1554, and chancellor of France in 1560. To his moderate policy were due the edict of Romorantin, 1560, which prevented the introduction of the Inquisition in France; the edict of pacification, 1562, authorizing the free exercise of Protestant worship; and the ordinance of Moulins, 1566, which aimed at reform in the administration of justice. Distinguished for his integrity and moral courage, L'Hôpital stood far in advance of his time in his support of toleration and civil liberty. He gave up his office in 1568.

Li, lē, or Cash, a copper coin of China, with a square hole in the middle, and an inscription on one side. The value of a li in American money is about $\frac{1}{8}$ of one cent. Li is also a Chi-

nese measure of length equal to about one third of an English mile.

Li Hung Chang, lē hoong chāng, Chinese statesman and diplomatist: b. Lu-chow, province of Ngan-hwei, 16 Feb. 1823 (or perhaps 1819); d. Peking 7 Nov. 1901. He received a thorough education, passing through the successive grades of scholarship, with the severe examinations which in China must be undergone before admission to the literary caste, "ahead of 15,000 competitors". In 1847 he received the third degree, and entered the Hanlin College in 1849. In 1850, when the Tai-ping rebels invaded Ngan-hwei, he joined Tseng Kuo Fan's army as secretary. He was appointed judge of Chekiang province, and in 1861 governor of Kiang-su. In 1863, in conjunction with Colonel (afterward General) Charles George Gordon (q.v.), known as "Chinese Gordon", he retook Su-chow, and drove the rebels entirely out of Kiang-su. Gordon's force, the "Ever-victorious Army", had previously been commanded by Frederick T. Ward, an American soldier of fortune, and was largely composed of foreigners. From them Li Hung Chang derived much information concerning Europeaus, and also acquired increased military knowledge and ideas of western political ethics. For his services in suppressing the Tai-ping rebellion Li was made commander of the imperial forces, head of the navy, a hereditary noble, and received the highest decorations in the gift of the emperor. In 1864 he was appointed governor of the Kiang provinces. During the Nien-fei rebellion (1868) he was degraded for apathy in the face of the enemy, but was soon restored to favor. In 1872, after the massacres at Tien-tsin, followed by his stern measures of redress, he was appointed viceroy of Chi-li, the metropolitan province. During his long service in that office he resided at Tien-tsin, where he displayed his progressive designs by many improvements, among which were a great canal and the forming of the Chinese Merchants' Steam Navigation Company. Here for 24 years (1870-95) he exercised a power in reality second only to the emperor's, controlling the foreign policy of the empire, and introducing modern tendencies from western civilization. He negotiated important treaties with Japan, Peru, and other countries, increased the military strength of China in view of foreign encroachments, and may be said to have created the Chinese navy. He was imperial commissioner of trade for the northern ports; the emperor entrusted to him supreme charge of the military and naval forces sent to Korea in the Chino-Japanese war; and though several times distrusted and disgraced, he bore nearly the whole burden of the war, marine, and financial departments of the Chinese government. During the war with Japan the disasters to the Chinese armies and navy were laid to his charge, and he was degraded and punished, but still retained his office of prime minister. He was sent to Japan in 1895 to negotiate the peace treaty, and barely escaped assassination. Having represented China at the coronation of Nicholas II. of Russia in 1896, he made a tour of the world, and was everywhere received as a highly distinguished guest. After the suppression of the uprisings of 1900-1 he played a prominent part in adjusting the relations of China with foreign powers.

LI HUNG CHANG.

LI HUNG CHANG.

LIBBEY — LIBERAL REPUBLICAN PARTY

imports colonial produce, manufactured goods, coals, etc. Pop. (1897) 64,505.

Lib'bey, William, American scientist: b. Jersey City, N. J., 27 March 1855. He was graduated from Princeton in 1877 and since 1880 has been professor of physical geography there. He is a fellow of the geographical and geological societies of London and Paris.

Lib'by, Laura Jean, American novelist: b. New York 22 March 1862. She was married to Van Mater Stilwell in 1898. Her earliest writings were contributed to the New York Ledger and other story papers. Among her many fictions are: 'Lovers Once but Strangers Now'; 'When His Love Grew Cold.' The literary merit of her work is very slight.

Libby Prison, a famous prison at Richmond, Va., during the Civil War. It was a large brick structure named for its owner who used the building as a ship chandlery before the War. The Confederate government early secured it as a military prison for Federal soldiers, and many thousands were confined here. In 1863 and 1864 there were many deaths from disease and lack of food. In 1892, the building was torn down and removed, brick by brick, to Chicago, and set up there as a museum, but the enterprise proved a failure.

Libel, (1) a defamation of a person, with malice expressed or implied, made public by means of writing, printing or pictures, calculated to provoke him to anger, or expose him to hatred, ridicule or contempt. Spoken words, however opprobrious or injurious, do not amount to libel but are classed as slander; and, being more limited in their publicity, the offense is not so great as in a case of libel. There may be a libel by traducing the memory of one who is dead, as well as one which attacks the reputation of one who is living. Any publication which has a tendency to disturb the public peace or good order of society, is actionable as a libel, and may usually be prosecuted by either a civil action for damages or by a criminal proceeding, and both remedies are often pursued at the same time. In the absence of some statutory provision on the subject, proof of the truth of the matter contained in the libel does not ordinarily furnish a good defense to the offending party. The publication may be very limited and yet amount to the offense. The malicious reading of a libel to one or more persons has been held sufficient and the sale of each copy of a book containing a libel has been pronounced by a court as sufficient to furnish a distinct offense. Libels against the government consist of calumnious publications in denunciation or unwarrantable criticism of the established governmental system or in censure of methods of administration, provided the allegations are of such a nature that their natural tendency or evident purpose is to promote disaffection among the citizens or to excite a spirit of revolution. But indictments for libels of this character are very rare, and would not be resorted to except in extreme and very plain cases. Many of the States have enacted statutes upon the subject of libels, declaratory of the old common law rules, with ancillary provisions, relating principally to forms of administration, with provisions as to punishment. A libel may be a misdemeanor

only, or a felony, according to the character of the offense.

(2) Libel in admiralty practice denotes the complaint or pleadings by which an action is commenced, to enforce some claim or right in a marine matter, and contains a circumstantial statement of the claim. The general scope of the jurisdiction of admiralty embraces all marine contracts and maritime torts, including captures in time of war, and seizures for revenue forfeitures, and all duties appertaining to marine commerce and general navigation. The test of jurisdiction in torts is determined by the place where the same were committed. Such a libel is not required to be drawn with any degree of technicality, the substance being more important than the form. In the United States substantially all admiralty matters are transacted in the Federal courts. The plaintiff, or moving party in an admiralty proceeding, is called the libellant, and the defendant, or party against whom the proceeding is brought, is termed the libatee or respondent. Sometimes a libel is directed *in rem* or against property only, without naming a respondent.

HENRY HARDWICKE.

Liberal Party, in politics, the party which claims to be distinctively that of reform and progress with a view to vast increased political power in the people, and to extend privileges to the masses. Most European countries have a liberal party, but in several of them, such as Germany, Belgium, and France, liberalism has lost heavily owing to the rapid spread of socialist doctrines, which involve economic and industrial rather than political reform. In Great Britain, Liberal and Conservative ministries follow each other at irregular intervals, and on the whole the system has worked well. The greatest of modern Liberal leaders was Gladstone, but his introduction, in 1886, of the Irish Home Rule and Land Purchase Bills alienated many of his supporters, and led to the formation of the Liberal Unionist Party. On the question of the war policy in South Africa in 1899-1901 the Liberal opposition was split into several groups, such as the Liberal Imperialists, who supported the government; the so-called "pro-Boer" Liberals, who opposed the war throughout; and those who, like Sir Henry Campbell-Bannerman, tried to combine both policies.

Liberal Republican Party, in American politics, a party organized in 1872 by Republicans, who were dissatisfied with General Grant's first administration as President. At a convention held by them in Cincinnati, in that year, Carl Schurz was elected its president, and a platform adopted demanding civil service reform, local self-government, and universal amnesty, recognizing the equality of all men, recommending the resumption of specie payment, etc. Horace Greeley and B. Gratz Brown were named for President and Vice-President. This platform and these nominations were adopted by the regular Democratic convention of that year, but dissensions arose, and other candidates were nominated, the result being that the Republican nominee, General Grant, was elected by an overwhelming majority and the Liberal Republican party was thereafter practically dead. The real strength of the party lay in its presidential candidate, Horace Greeley, who had

LIBERAL UNIONIST PARTY — LIBERIA

a large following, particularly of the farming element throughout the country, which was secured through the large and widespread circulation of the New York 'Weekly Tribune,' of which Greeley was the editor. See also GREELEY, HORACE.

Liberal Unionist Party, in British politics, a party formed in 1886 by the Liberals under the leadership of the Marquis of Hartington who objected to Gladstone's Irish Government and Land Purchase bills, as being dangerous to the empire. They gained their immediate object by coalescing with the Conservatives, and in the election which followed the defeat of the Gladstonian ministry they succeeded in returning some 80 members to parliament. They have since acted with the Conservatives.

Liberator, The. See GARRISON, WILLIAM LLOYD.

Liberia, li-bē'ri-a, Africa, a negro republic on the west coast between Sierra Leone and the Ivory Coast. A convention with France in 1892 fixed the Cavally River as the southeastern boundary, and restricted the inland territories of the republic. The area is estimated at 35,000 square miles. It was founded as a colony of free blacks by the American Colonization Society in 1820, under the philanthropic idea that many, if not all, of the liberated slaves would prefer returning to Africa to staying in America, where, at that time, they were denied political rights. Liberia was declared an independent state in July 1847, and in the following year was recognized as such by Great Britain and France, when a treaty of trade and commerce with the state was concluded. A large proportion of the inhabitants speak English. The government of the country is on the model of that of the United States, consisting of a president, a vice-president, a senate, and a house of representatives. It is provided that on the increase of the population each additional 10,000 shall have a representative. For political and judicial purposes the republic is divided into counties and townships. The counties are four in number, and called Montserrado, Grand Bassa, Sinoe, and Maryland. Each town is a corporation, with elected municipal officers. Monrovia (pop. 13,000), the capital and port of the colony, is situated on Cape Mesurado. There are besides a number of towns or villages in the territory.

The general line of the coast (about 500 miles) is from northwest to southeast. There are several inlets and harbors at Cape Mount, Cape Mesurado, Cape Palmas, and Bassa Cove. There are many rivers, of which the principal is the St. Paul, which enters the ocean at Cape Mesurado. It is about half a mile wide, and at low tide has seven feet of water on the bar at its mouth. It is navigable only about 18 miles from the sea. The other largest rivers are the St. John, which empties at Bassa Cove; the Junk River, which runs between the St. Paul and the St. John; Cape Mount River, which flows into the sea at Cape Mount; and the Grand Sesters, east of the St. John, which has 14 feet of water over the bar at its mouth. The land on the coast is generally low and sandy, except near the capes, which are elevated, and in the southeast, where the shore is bold and rocky. From the coast the land gradually rises, until at the distance of 30 miles inland it swells into

forest-covered hills, and in the remoter interior into mountain ridges divided by fertile valleys. The soil is generally good, though there is some poor land. It is of a yellowish color, and tinges the rivers which flow through it. There is little swamp land, the country being almost universally broken and rocky or gravelly. The climate is that common to regions near the equator. There are two seasons, the wet and the dry. The former begins with June and ends with October. Rain falls during the greater part of this season, though not without intervals of clear skies and successive days of fine weather, especially in July and August. In the dry season rain is rare, though there are occasional showers. The average heat of the year in Monrovia is 80° F., that of the rainy season being 76° and of the dry 84°. The mercury seldom rises above 90° in the shade and never falls below 60°; the daily variation seldom exceeds 10°. June is the coolest month, and January the hottest. During the hottest months, January, February, and March, the heat is mitigated by the constant winds, the land breeze blowing from midnight until near midday, and the sea breeze from midday until near midnight. The climate both on the coast and in the interior is deadly to the white man, and though less fatal is still formidable to the black man born and reared in temperate regions. To the white man there is no acclimation in Liberia; the first attack of fever does not secure him from subsequent attacks. To the natives the climate is not unfavorable; they are robust and have few diseases, and many of them live to a great age. Iron ore abounds in Liberia, and copper and other metals exist in the interior of the country. The vegetables are almost endless in their variety. The most important of the native trees are rosewood, teak, mahogany, hickory, poplar, brimstone wood (so called from its yellow color), sassa wood, and many others valuable in ship-building and cabinet work. Camwood and other dyewoods, ebony, the acacia which yields gum-arabic, and the copal trees are found. There are several varieties of palm, all highly useful, especially the nut-bearing palm from which palm oil is made. Medicinal plants abound; among them are the copaiba tree, the *Croton tiglium*, which yields the croton oil, the castor oil plant, and the *Ricinus major*, whose seeds produce a highly purgative oil, and whose wood is much used for hedges and fences. Several varieties of maize and rice of excellent quality are cultivated, and on the highlands of the interior good crops of wheat, barley, and oats have been raised. Cotton flourishes, and sugar-cane and excellent coffee are easily produced. The esculent and farinaceous roots chiefly cultivated are the sweet potato, the cassava, the yam, the tenia, which in flavor resembles the potato, and the arrowroot. Cabbages, beans, peas, tomatoes, beets, cucumbers, and almost all the common garden vegetables known in America, thrive when planted in the proper season. The fruits are numerous and fine. Among them are the mango, lemon, lime, orange, guava, tamarind, pomegranate, cocoanut, plantain, banana, rose apple, African cherry, pineapple, avocado pear and the African peach. Wild animals are scarce, the elephant, hippopotamus, leopard, crocodile, boa constrictor, and deer, formerly abundant, being now rarely met with. Monkeys, guanas, chameleons, lizards, and ants in great

LIBERIUS — LIBERTY BELL

variety, abound in the forests. The driver ants, which travel from place to place in countless multitudes, are welcomed by the people, for when they enter a house they soon clear it of every other species of insect and vermin. The Liberians build coasting-vessels, and possess a number of large vessels trading with Great Britain and the United States. An export and import trade is carried on, and a large number of the inhabitants of the interior depend upon Liberia for their supplies of European goods. The more important articles of export are coffee, sugar, palm-oil and palm kernels, cocoa, arrowroot, caoutchouc, ivory, kola nuts etc. The total value of the trade, however, does not probably exceed \$2,500,000.

The population amounts to 2,060,000 of whom 60,000 are liberated American slaves and their descendants, the remainder indigenous negroes, including the Kroomen (q.v.). No white man is allowed to acquire citizen's rights or to hold property. There is no standing army, but all citizens capable of bearing arms are enrolled in the militia. Slavery is declared illegal. Complete religious toleration exists, the Methodist forms prevailing. English money is current, though accounts are kept in dollars and cents; and English weights and measures prevail. The financial condition of the republic has been deplorable; latterly there has been a change for the better. In 1893 the revenue derived chiefly from customs duties was \$185,345 while the expenditure mainly for administrative purposes was \$188,187, in 1900 the revenue was \$218,804, and expenditure \$207,935. The state debt contracted in 1871 amounted to \$500,000 at 7 per cent on which the unpaid interest alone in 1899 amounted to \$892,500. In that year an agreement was effected for the reduction of the rate of interest, the amortisation of the principal, and the payment of arrears; duties on rubber and other articles being assigned as security. In 1902, by this arrangement the debt amounted to \$391,250 and the arrears of interest to \$93,735. The arrears of interest on the internal debt, however, exceed the principal. The republic unfortunately is not in great favor with the native negroes, nor with those of the United States, although a few immigrants still arrive annually. Not only have the Liberians failed to make any impression on the aboriginal inhabitants, whom they were supposed to civilize, but, notwithstanding many honorable exceptions, they are lazy and quarrelsome, and unfortunately there is a general tendency in many respects to relapse into barbarism. About six square miles only of the territory is effectively administered. Consult, Blyden, 'A Chapter in the History of Liberia' (1892); Bourzeix, 'La République de Libéria' (1887); Büttikofer, 'Reisebilder aus Libéria' (1890); Delafosse, 'La République de Libéria' (1900); Durham, 'The Lone Star of Liberia' (1893).

Liberius, pope: b. Rome; d. there 24 Sept. 366. He was pope from 352 to 366; is one of the pontiffs that have incurred the accusation of heresy. It is conceded that he suffered an exile of two years by order of the Emperor Constantius for refusing to subscribe to a condemnation, by the Council of Arles (354), of the great champion of the Niceno-Constantinopolitan creed of the homoousion, St. Athanasius. But it is alleged that he obtained his recall by subscribing to a heretical, formally Arian con-

fession of faith drawn up by an assembly of bishops at Sirmium. As there were three councils of Sirmium and three Sirmian confessions, the question arises, what was the tenor of each, and which one was subscribed by Liberius. The first council was held in 351; its confession is orthodox in its terms, but it does not employ the orthodox shibboleth homoousion. The second was held in 357: its confession is emphatically Arian. The third confession is Semi-Arian and heretical: but as it was formulated in 358, after Liberius' return from exile, that could not be the confession signed by him. Did he sign the second? No; for St. Hilary (300-368) a principal authority for these transactions, states that the confession signed by Liberius was drawn up by 22 bishops, among them Demophilus; and Liberius himself says that it was formulated by eastern bishops and presented to him by Demophilus, one of them: the confession signed by Liberius must have been this first (and orthodox) Sirmian confession; for the second was the work of western bishops or approved by them—Valens, Ursacius, Hosius, Germinius and Potamius.

Libertad, lē-bēr-tād', Peru, a department bordering on the Pacific Ocean, with the departments of Lambayeque, and Cajamarca on the north, Loreto on the east, and Ancachs on the south. It is mountainous, with a narrow strip of level land along the coast. The Marañon, the head stream of the Amazon, waters its eastern slopes. Area, 10,206 square miles; pop. (1896) 250,931. Capital, Trujillo.

Lib'ertas, the goddess of freedom. By the Greeks she was invoked by the synonymous title Eleutheria. At Rome, her most famous temple was situated on the Aventine Mount. She was represented under the figure of a woman holding in one hand a cap, the symbol of liberty, and two poniards in the other. In ancient times Roman manumitted slaves put on what was termed the Phrygian cap, in token of their freedom. In modern times, a cap is also used as a symbol of liberty; thus, in France, a red cap formed the badge of the Jacobin Club. In England, a blue cap with a white border is used as a symbol of the constitutional freedom of the nation.

Lib'ertines, or **Liberti'ni**, a sect of fanatics in the 16th century in the Netherlands and Belgium, who maintained that nothing is sinful but to those who think it sinful, and that perfect innocence is to live without doubt. They advocated community of goods and gave themselves the name of "Spirituals." The name was also applied in England to the early Anabaptists about the middle of the 16th century.

Lib'erty, Mo., city, county-seat of Clay County; on the Hannibal & St. J. and the Chicago, M. & St. P. R.R.'s; about 15 miles, by rail, northeast of Kansas City. It is situated in an agricultural region, and its chief manufactures are flour and dairy products. Its trade is principally in grain, vegetables, fruit, and live-stock. It is the seat of the William Jewell College, opened in 1849 under the auspices of the Baptists, and of the Liberty Ladies' College opened in 1890. Pop. (1900) 2,407.

Liberty Bell, the bell which formerly hung in the dome of the old State House (Independence Hall), Philadelphia, and was rung

LIBERTY BOYS—LIBERTY, STATUE OF

to announce the signing of the Declaration of Independence, 4 July 1776. It was cast in England especially for the State House, and was brought from there in 1752; in being taken from the ship it met with an accident which spoiled its tone, and it was recast in Philadelphia in 1753, when the words "Proclaim liberty throughout all the land unto all the inhabitants thereof" were inscribed on it. When the British occupied Philadelphia, the bell was taken down and hidden in the Delaware River near Trenton, but was afterward hung in its old position, and for several years rung every Fourth. In 1835 it was broken while tolling for the death of Chief Justice Marshall. In 1834 it was placed in the hall of the old State House on a pedestal with 13 sides representing the number of original States. In 1893 it was carried to Chicago for the World's Fair, and in many cities through which it was carried was greeted with special demonstrations; and has since been specially exhibited in other cities. Consult: Belisle, "History of Independence Hall."

Liberty Boys, a popular name given the Sons of Liberty during the American Revolution.

Liberty College, a coeducational institution, founded at Glasgow, Ky., in 1875, under the auspices of the Baptist Church. In 1902, the number of instructors connected with the school was 11 and the number of pupils 250. The grounds and buildings were valued at \$25,000. The amounts received from tuitions and other fees were \$6,500.

Liberty, Equality, Fraternity, a well-known motto of the French Republic, dating from the time of the first revolution. Equality, in this connection, means equality before the law and the absence of class privileges. The motto gives title to a work by Sir J. F. Stephens (1873).

Liberty Party, the first political organization of the American Abolitionists (q.v.). The Anti-Slavery Society was composed of two wings steadily and at last decisively diverging: the politicals, who wished the work to be carried on as other reform measures are, by massing its supporters, and either winning a decisive victory or extorting gradual compromises from its opponents; and the Garrison wing, who refused to vote, hold office, or in any way recognize a government which legitimated slavery, denounced the Constitution, and denounced the churches and ministers for refusal to join the movement. The violence of this branch, and even more the revolutionary and sometimes offensive social theories associated with it, made the other anxious to part company; and they brought this about by having the annual report in 1838 suggest the nomination and support of abolitionist candidates. The next year, on the refusal of the Garrisonians to listen to this, the political wing split away, and in 1840 organized the "American and Foreign Anti-Slavery Society." Among the leaders of this secession were James G. Birney, Arthur Tappan, Gerrit Smith, J. G. Whittier, Edward Beecher, John Jay, and Thomas Morris. In a convention at Warsaw, N. Y., 13 Nov. 1839, this branch nominated Birney (a Kentucky ex-slaveholder) for President, and Francis J. Lemoyne for Vice-President. A national convention (mainly from New York) was held 1 April 1840, confirmed

these nominations, and took the name of the Liberty party. The nominees refused to accept, but were voted for none the less, and received 7,059 votes in the Harrison-Van Buren election of 1840, of which 2,798 were from New York State. During the next four years the party put up tickets in various local elections. On 30 Aug. 1844 it held another national convention at Buffalo. Polk was already nominated by the Democrats, on the issue of Texas annexation, which Clay had dodged and secured the nomination by the Whigs; but the Liberty Party had pronounced against all ostrich policies or candidates, and nominated Birney again, with Thomas Morris of Ohio as Vice-President. They received 62,300 votes, all in the North and Northwest, 15,812 in New York. Small as this vote was, it turned the scale in New York and Michigan against Clay, and elected Polk, the Southern Democrat; decided the annexation of Texas, and reinforced the slave party with new territory six times the size of New England. This result, however it might prove the potential power of the party, was not wholly satisfactory, and it was evident that a pure Abolitionist party was premature. The Abolitionists, therefore, dropped their separate organization, and in 1848 and 1852 voted for the candidates of the Free Soil Party (q.v.) accomplishing much more by strengthening the forces of this practical movement, whose enemies were constantly playing into their hands, than they could have done with the other. After the rise of the Republican party they formed part of its reliance and its advance guard, but always with a certain separation of feeling and even of organization.

Liberty, Statue of, the name of a colossal statue on Bedloe's Island in New York harbor. On 28 Oct. 1886, after more than 12 years of preparation, this statue, given by the people of France to the United States, was dedicated and unveiled. The statue was the conception of M. Bartholdi, who designed it for the Franco-American Union in 1874. It was built by popular subscriptions in France, and required over five years for its completion. It was mounted in Paris in October 1881. The American pedestal for the statue was not commenced till April 1883, and was finally finished in 1886. This was built by popular subscription. The statue was erected on an iron framework bolted firmly to the stone pedestal. The statue, which is of bronze, is of the following dimensions:

	Ft. In.
Water-level to top of pedestal.....	<u>.149</u> <u>10</u>
Statue proper to top of torch.....	<u>.151</u> <u>5</u>
Total height from water-level.....	.301
Heel to top of head.....	.112
Length of hand.....	.16
Index-finger8
Circumference at second joint.....	.7
Size of finger-nail.....	13 x 10 in.
Head from chin to cranium.....	.17
Head-thickness from ear to ear.....	.10
Distance between the eyes.....	.2
Length of nose.....	.4
Right arm, length.....	.42
Right arm, greatest thickness.....	.12
Thickness of waist.....	.35
Width of mouth.....	.3
Tablet, length23
Tablet, width13
Tablet, thickness2

The statue weighs 450,000 pounds, or 225 tons; the bronze alone weighs 200,000 pounds. Forty persons can stand comfortably in the

LIBERTY TREE—LIBRARIES

head, and the torch will hold 12 people. The number of steps from the base of the foundation to the top of the torch is 403; from the ground to the top of the pedestal 195 steps. The number of steps in the statue from the pedestal to the head is 154, and the ladder leading up through the extended right arm to the torch has 54 rounds. The cost of the statue is estimated at \$250,000; the cost of the pedestal and the erection of the statue \$350,000; total cost of the work, completed \$600,000. The light in the torch at the top of the Statue of Liberty is maintained by the Lighthouse Service of the government. Liberty exceeds in height the Colossus of Rhodes which was said to have been about 105 feet high. That of Nero is said by Suetonius to have been 120 feet high. The statue of Charles Borromeo, which is still standing on the Lake of Geneva, is 66 feet high, and is mounted on a pedestal measuring 46 feet. The celebrated statue of Jupiter carved by Phidias is said to have been 60 feet in height.

Liberty Tree. (1) a famous ballad of the Revolutionary War, written by Thomas Paine in 1775. (2) An old elm tree in Boston upon which the citizens hanged in effigy British officials connected with the Stamp Act and its enforcement.

Libi-divi, lē'bē-dē'vē. See *Divi-divi*.

Libmanan, lib-mà-nan, or Libanan, lē-bà'nàn, Philippines, pueblo of the province of Ambos Camarines, Luzon, situated on the Polanluna River near its confluence with the Naga, 10 miles northwest of Nueva Cáceres. It is on the main road, and is a telegraph and military station. It has also important hemp and rice industries. Pop. 14,500.

Li'bra, (1) the ancient Roman pound weight, consisting of 12 ounces. (2) The original meaning is balance or pair of scales. (3) The seventh sign of the zodiac is called Libra, because at its first point the ecliptic crosses the equator to the southern hemisphere, and we have then the autumnal equinox, when day and night are, as it were, equally balanced.

Libraries, a general term used to designate collections of books and manuscripts for reading and preservation. The term library is also commonly applied to any apartment or building containing such a collection of books or manuscripts.

Libraries of the Ancients.—In early antiquity libraries consisted of archives, which were preserved in the sacred temples. The oldest library is said to have been founded in Memphis by the Egyptian king Osymandyas, of the 12th dynasty. It was housed in a division of the palace, at the entrance of which were inscribed the words: "The Healing of the Soul." It contained works of an unknown antiquity deemed sacred by the Egyptians, which were destroyed in the ravages attending and following the Persian invasion. The monumental cuneiform records of the ancient Assyrian, Babylonian, and Persian empires have been designated "public libraries in clay." The principal Hebrew library was in the temple at Jerusalem; it was restored after the captivity by Nehemiah, and again by Judas Maccabæus, and perished in the conquest by the Romans.

In Greece, Pisistratus was, according to Aulus Gellius, the first to establish a public library at Athens. It was taken to Persia by Xerxes, returned by Seleucus Nicator, pillaged by Sylla, and restored by Hadrian. Polycrates soon after founded a library in Samos, and large collections of books were made by Euclid, Euripides, and especially by Aristotle, whose library, after passing through two generations, was purchased by Ptolemy Philadelphus and transported to Alexandria. Of ancient libraries, the most celebrated was that at Alexandria, which at one time is said to have contained 700,000 volumes. (See *ALEXANDRIAN LIBRARY*.) The first library at Rome was that of Paulus Æmilius (167 B.C.), the booty of war in Macedonia. Libraries subsequently became common, and in the time of Augustus it was fashionable for men of culture to have one in their houses. Sylla took from Athens to Rome the library of Apellicon the Teian; Lucullus made a large collection, and his galleries and porticoes became a favorite resort for conversation; Varro, Atticus, and Cicero were enthusiastic collectors of books. One of the unfulfilled projects of Cæsar was the formation of a public library, which should contain all the works in Greek and Latin literature. Augustus established the Octavian and Palatine public libraries, the latter of which continued until the time of Pope Gregory I. More important was the Ulpian library, founded by Trajan. In the 4th century Publius Victor mentions 28 public libraries in Rome, beside many valuable private collections. All of these perished in the storms of barbarian invasion. The library of Constantinople, founded by Constantine, and enlarged by Julian and the younger Theodosius to the number of 120,000 volumes, was partially burned by the iconoclasts in the 8th century under Leo the Isaurian. Libraries were founded from the 9th to the 11th century, especially by the imperial family of the Comneni, in the cloisters on the islands of the archipelago and on Mount Athos. After the fall of the Byzantine empire the imperial library was preserved by the command of Mohammed II. in one of the apartments of the seraglio, and was either destroyed by Amurath IV. or perished by neglect. The Moslems had an important library of Arabic books in Alexandria, and one at Bagdad, which included Greek manuscripts.

Mediaeval Libraries—As early as the 12th century Spain had upward of 70 libraries, and no monastery was founded without a collection of books, sacred and secular. The Benedictines had celebrated collections at Monte Casino, Canterbury, York, Bobbio, and Corbei. There were others at Fulda, Hirschau, Tours, Saint Germain des Prés, and Saint Gall. The revival of classical learning gave a new impulse to the formation of libraries. The large universities, princely families and many private scholars were zealous collectors. With the invention of printing began a new era in library history, the number of books being greatly increased and the cost materially reduced. Several of the largest libraries in Europe date from this period. The suppression of the numerous cloisters caused many small libraries to be incorporated in the larger collections of universities and cities. (See *Book*.) Nicholas V. during this mediæval period founded the library at the Vatican. Among others early founded was the Bodleian at Ox-

LIBRARIES

ford (1597); the University at Cambridge (1475); the University at Edinburgh (1580); the Imperial at Paris (1377); the Town at Strasbourg (1531); the Royal at Munich (1550); the Royal at Copenhagen (1550); the Laurentian at Florence (1444); the Saint Mark's at Venice (1468); the University at Turin (1436); and the Town at Brussels (1350).

Libraries in Great Britain.—In Great Britain the two largest libraries of modern times are the Bodleian in Oxford, so named after its founder, the diplomatist and scholar, Sir Thomas Bodley (1545–1613), and now containing probably about 570,000 volumes and 30,000 MSS.; and the library of the British Museum at London, now one of the first in the world, and containing probably more than 1,900,000 printed books and perhaps 100,000 MSS. and charters. The library of Cambridge university is estimated at over 500,000 books and 6,500 MSS. Perhaps the fourth library in Britain in point of value is the Advocates' Library in Edinburgh, with about 350,000 books. The four Scottish universities have collections respectively of from 100,000 to 180,000 volumes. The most valuable library in Ireland is that of Trinity College, Dublin, with 240,000 volumes. Important free libraries have been established at Liverpool, Manchester, Birmingham, and Hull, which have each a library of over 100,000 volumes. These free libraries were the result of a Free Library Law passed by Parliament in 1850.

Modern European Libraries.—The principal libraries of modern times on the European continent are: the national library at Paris, about 2,600,000 printed books and 102,000 MSS.; the royal library at Munich, about 1,000,000 books and 40,000 MSS.; the royal library at Berlin, about 1,000,000 books and 30,000 MSS.; the imperial library at Saint Petersburg, with a total number of volumes about 1,100,000 and 28,000 MSS.; the Strasbourg University and public library, 760,000 volumes; the imperial library at Vienna, with more than 500,000 books and 24,000 MSS., and the university library with 559,000 books; the university library at Göttingen, having 500,000 books; the royal library at Dresden, 500,000 printed books and over 6,000 MSS.; Hamburg city library, 600,000 books and 5,000 MSS.; Leipsic University library, 500,000 books and 5,000 MSS.; the royal library at Copenhagen, now said to have more than 500,000 books and 20,000 MSS.; the royal library in Stockholm and the library of the University of Upsala, in Sweden (280,000 to 300,000 each); the national library in Madrid, 500,000 volumes; the royal library at Brussels, more than 375,000 books and 27,000 MSS.; the royal library at Stuttgart, 432,000 volumes; the Vatican library at Rome, with printed volumes estimated at over 200,000, and 26,000 MSS. Besides the national library, there are in Paris those of the Arsenal (454,000 printed books, 6,000 MSS.), of Saint Geneviève, of the Institute, and the Mazarin library (300,000). In the rest of France there are over 270 public libraries, the principal of which are those of Lyons (160,000 volumes), Bordeaux (200,000), Aix (170,000), etc. Access to these great collections is easily obtained both by natives and foreigners. In Italy there are a great number of valuable libraries, of which the university library at Bologna is said to contain 255,000

volumes, 6,000 MSS.; the National Library at Florence, 450,000 volumes, 15,000 MSS.; besides the Laurentian library in the same city, consisting almost entirely of MSS.; the university library at Genoa, 120,000 volumes; the Ambrosian at Milan, about 170,000 printed volumes and about 8,400 MSS.; the national library in the same city containing about 230,000 volumes; that at Parma 200,000 volumes, that of Naples 357,000, and that of Saint Mark at Venice 403,000. The Victor Emmanuel Library at Rome, consisting of the old library of the Jesuits, augmented by the libraries of suppressed monasteries, has over 550,000 volumes; the Casanata library, also at Rome, is said to contain 160,000 volumes, the Biblioteca Angelica 150,000 volumes, the Barberini library 100,000. The French government in the 19th century established over 25,000 popular libraries in connection with primary schools.

Libraries in America.—Soon after the Puritans landed at Plymouth Rock they founded a college and with it a library. The Harvard College Library established in 1638 was followed by Yale and William and Mary in 1700. The Philadelphia Library was founded in 1731, that of the American Philosophical Society (q.v.) (1742); the Charleston, S. C., Library (1748); the Athenaeum at Providence (1753); the Society Library in New York (1754); New York Historical (1804); and the Boston Athenaeum (1804). In 1800 the Harvard College Library had only 12,000 volumes; the largest, the Philadelphia Library Company, after absorbing three similar libraries, had only 18,391; the New York Society Library had 5,000; Yale College had only 2,700; and the Charleston Society Library had reached 7,000. These were the giants; no other library had 2,500; not half a dozen had 1,000; the average was 500 volumes.

A new era in American library history began in 1833, when a Unitarian clergyman at Peterborough, N. H., founded a free circulating library by an appropriation that has been continued annually to this day. Thus America became the birthplace of the free library, for the leaders of the movement which resulted in the Free Library Law of 1850 in England have said that they derived the idea from this country. In 1847 another small town, Orange, Mass., opened a free library, and four years later Wayland, Mass., followed. Then came the passage of the acts by which New Hampshire in 1849, and Massachusetts in 1851, authorized any town to tax itself for a free public library. In 1835, a law of New York permitted each school district to tax itself \$20 to found, and \$10 a year to maintain, a free public library. But as the people would not tax themselves, the friends of the measure persuaded the Legislature in 1838 to appropriate \$55,000 a year to purchase the books. Fifteen years later the libraries had over 1,600,000 volumes, but they were very little used, except in the cities, and the system was an entire failure.

Meanwhile other great libraries were being established in the larger cities. The New York Mercantile was founded in 1820; the Astor (q.v.) in 1839, and the New York State at Albany in 1818. Others established were the State at Annapolis, Md. (1826); the State at Indianapolis (1825); the Boston Public, (1852); the Congressional, at Washington (1851), and

LIBRARIES — LIBRARY ADMINISTRATION

the Smithsonian, at Washington (1849). Until 1876 these institutions and the smaller libraries worked along individual lines with no thought of organized effort, or of comparing views or adopting common plans for library improvement. But in 1876 the American Library Association was formed and the publication of the 'Library Journal' commenced. Since that date development in Library Science has been rapid, there being five divisions in which there has been the most progress — library establishment, the profession, the building, the management, and the methods of reaching the public. The trend of opinion has been toward libraries established by legislation, supported by taxation, helped as far as possible by private generosity, managed by their own authorities, free to all, the library of the people, by the people, for the people. To assist their establishment, 17 State library commissions were organized, the first in Massachusetts in 1890.

The gifts to libraries by private individuals between the years 1893 and 1903, originating, perhaps, in the persistent solicitation of college presidents, have been remarkably generous, the total amounting to many millions of dollars. Most of these donors, however, have preferred to give buildings and land rather than books, or funds for buying books. (See CARNEGIE, ANDREW.) The growth and development of the Boston and Chicago public libraries; the wonderful progress of the Congressional Library (q.v.) at Washington and the consolidation of the Astor (q.v.) and Lenox (q.v.) libraries and the Tilden Foundation into the great New York Public Library (q.v.), are the chief events in the library history of the present day.

Libraries, Traveling. See TRAVELING AND PICTURE LIBRARIES.

Library Administration. In recent years the conception of a library's field and functions has grown so rapidly that library administration has become a recognized science with problems vastly broader and deeper and demanding well equipped professional schools giving systematic instruction to those in whose charge the leading libraries will be placed.

This has greatly altered the librarian's status. Once he was little better than a head janitor whose functions were to keep the books clean and protected. Now the New York State library school, the first of its kind in the world, admits no candidate to its two years' course who is not a college graduate and in addition gives promise of more than ordinary success. In salaries, hours of service and vacations the librarian is rapidly winning his place beside other educational officers, as the public recognizes that in general education, professional training, executive capacity and all the factors which determine salary, the successful modern librarian takes full rank with the highest educational officer of the same community. The proper salary of a college librarian is now that of a full professor. In a university he ranks with deans of departments and in public libraries with superintendents of schools or high school principals. Usual daily hours are now 7 and usual vacation one month, with a growing tendency to allow a second month for illness or other absences, so that a librarian who has lost no time during the year will have two months for

a long summer vacation, or somewhat over half what is enjoyed by most teachers.

Functions.—The chief function of the old library was to get all the books it could and preserve them safely. The modern library does this also, but has placed free public use infinitely above getting and keeping. First the word library lost its etymologic meaning from the tree bark on which writing was done, and came to mean any collection of books. It is now rapidly losing that sense and means the community intellectual headquarters where are to be found not only books and pamphlets, but periodicals, newspapers, maps, pictures, coins, medals and collections illustrating science, history or art. It is no longer a reservoir whose chief function is to take in and accumulate, but a fountain. Its work is no longer passive, but aggressive. The modern librarian is as anxious to put his wares before the public and have his books and other material used as is the store or factory to secure custom for its goods.

We have learned that reading is the greatest engine human genius has evolved. It grows constantly in importance. While most reading is better than most conversation, it is as powerful for evil as good, so that the greatest problem for educators and statesmen is to develop in youth a taste for the best reading and to supply it free through life.

Reading has three great functions: (1) To inform, so that one may stand on the shoulders of all his predecessors and utilize their labors and experience in any subject. This cumulative wisdom of the race passed on in books makes possible the marvels of civilization. Books give this information which builds material prosperity. (2) A still more vital function, but less tangible, is the inspiration which lifts up and builds character, the work of the books of power, the books of all time. (3) The last great function is to afford rest and recreation for the tired and overworked to fit them better to carry life's burdens. The free public library has been found the only practicable method for shaping this reading, which in its threefold form of information, inspiration and recreation is the greatest influence in modern life.

Administration.—Books and other suitable material are no more a library than a pile of bricks is a building, or a mob of men is an army. To be effective there must be such arrangement and organization that its great functions can be performed promptly and efficiently without undue cost. Experience proves that the chief factors in a successful library are in order of importance: (1) Librarian; (2) books; (3) methods; (4) building. Because it is most prominent and readily understood by the inexperienced, the least important is usually thought of first.

Library Buildings.—To compete successfully with places of amusement the library should be as accessible as possible, but preferably a few steps off the main street for greater quiet. Books increase in a ratio beyond the plans of architects and librarians, and not one library in a hundred makes sufficient provision for growth, either for books, readers, or administration. Good natural light and ample room for growth are essential. Steel, glass and brick are the best materials for large libraries, but fireproof construction is im-

LIBRARY ADMINISTRATION

portant only for central libraries which preserve rare books not readily obtainable in open market. The best books should be housed within easy walking distance of every citizen. This requires in larger towns branches or deliveries at convenient points. The most used books should be freely accessible in reading-rooms, but economy and convenience both demand that the main supply should be kept in stacks. The best standard type is made up of double-faced bookcases only 75 cm. apart, thus filling solidly with volumes all space not needed for access to them. Each case is eight shelves high and five tiers long, thus giving 80 shelves on its two faces. Each shelf is 75 cm. long, 20 cm. deep and 25.5 cm. high, thus taking all books up to the largest standard (8vo) which by library rules is limited to 25 cm. These cases make a one-story stack, with every book within reach of the hand without ladders. Wood is used for one or two stories, but steel is better for the taller stacks (sometimes 10 stories) and grows steadily in favor because it is strong, compact, fireproof and more open for light. The simplest satisfactory fireproof construction costs from 15 cents to 30 cents per volume of storage capacity. The plainest oak shelving can be built for about four cents a volume, while for temporary use the cheapest packing-boxes in four-shelf units 75 cm. long, each holding 100 volumes, can be made for 50 cents, the cheapest possible temporary storage.

Hot water heat is best. The boiler costs the same as steam, piping and radiation about 25 per cent more, fuel a trifle less. But steam is a less pleasant heat and is very apt to crack and annoy readers.

Artificial light should be provided on all reading-tables. High lights are bad for the eyes and unnecessary except for occasional illuminations. Acetylene gives a more perfect light, but the convenience of carrying flexible wires and turning on and off with a touch makes electricity almost the universal light where current can be bought cheaply. The stack section of the building should be of glass with only steel or masonry enough for support, with glass always opposite aisles.

Spiral stairs are costly, wasteful and inconvenient. Straight stairs under which space can be used for shelves take less space. Doors to bookcases are worse than useless and have been abandoned except for rare, costly or restricted books. Tables and desks should be 78 cm. high, not 75 cm. as usual; for short people can use higher chairs, but tall people cannot shorten their legs. Skilful arrangement of rooms will greatly reduce cost of administration. Permanent partitions should be used only where necessary for support. Temporary partitions, usually glass, can be readily moved as growth requires. These allow better light and supervision from another room, while shutting off noise, and give a more spacious look. Most important after the central rooms are: first a quiet study room, then a children's room. Even small libraries need one or more class or lecture rooms for clubs, classes and meetings which find their natural home at the library. Larger libraries require a growing number of special rooms for newspapers, art, patents and various other needs of the staff and public.

Selection of Books.—Counting only the

prominent nations, a new book is published every five minutes to swell the millions previously printed. Unbound books or pamphlets are almost beyond number. Besides the almost incredible number of daily, weekly, monthly and other periodicals, there are as many more institutions and societies constantly publishing papers, transactions and reports. Large libraries must make a liberal selection from these, complete, bind and preserve them for the use of posterity. The New York State Library alone receives 12,800 of these sequents. As every library is limited for money and space, it is a grave problem just what to buy and, except in cyclopedic libraries that take everything, what to accept as gifts. The need of printed guides has been partly met by bibliographies, catalogues and lists to help determine quickly what is best to buy, its cost, where and by whom published, and perhaps to track it through auctions and stores. Many think of these bibliographies as constituting a dozen or so reference books, but a reasonably complete collection numbers over 20,000 volumes and is growing as rapidly as other subjects. It is one great factor in the professional training of a librarian to learn how to use this extensive apparatus successfully.

Accessions.—After a book is selected, it must be made part of the completely organized library which has as its ideal the choice and delivery to each inquirer, with the least possible delay, of the book, pamphlet, article, essay or other item which then, there and to him will be most useful. This is a most difficult problem even in a small library, and in large ones with a million or more items from which to choose, no satisfactory results can be reached without an elaborately organized system, administered as carefully as are the details of a great factory or railway, where mistakes and carelessness are intolerable. There are 30 distinct steps in the accession department routine alone of a large library before a book is ready to be classified or catalogued. Economists have repeatedly tried to shorten the processes, but after a few years experience have been forced to incur the extra cost of going back and supplying omissions as the only way to avoid a more serious expense in the delays of hourly service to readers. Ownership is marked by a bookplate inside the front cover with name of library and official marks. The name is also repeated (stamped, embossed or preferably perforated) on the title-page so that it cannot be removed by book thieves, and most libraries have private marks at some special page, to be found only by one knowing the key, as a means of identifying lost or stolen books. Book numbers gilded on the back insure quick finding and replacing on shelves, and lending libraries usually put a manila pocket inside the back cover to carry the book or reader's card. The accession book is the business record. Every volume has a line across the two pages as its pigeonhole for its complete history. The columns are: number (in order of receipt), class number (showing subject), book number (showing place in that subject), volume number (if more than one), author, title, place and publisher, year when published, number of pages, size, binding, source (name of giver or seller), cost, with a final wide column for remarks on the book's history, for example, lost, worn out, sold, or withdrawn.

LIBRARY ADMINISTRATION

The accession number is stamped on first recto after title, on shelf list and cards, and exactly identifies that particular volume.

The shelf list is an inventory or brief list of all the library contains by subjects, and is usually kept on sheets laced in a binder, one sheet to each subject. Besides class, book, accession and volume numbers, it gives merely author and short title. It is used to take the annual inventory and is also a convenient form of subject catalogue, though it gives no cross references.

Author Catalogue.—This like all other catalogues and indexes is kept on cards 7.5 cm. high and 12.5 cm. long, the size adopted for national and international use and rapidly displacing all other sizes except for peculiar uses. (See LITERARY LABOR SAVERS, *Card Index System*.) The author catalogue gives under each name all of any author's work which the library has, without including any done by some one with the same initials or full name, thus confusing identity. This author catalogue is often expanded to include striking titles of anonymous books, names of subjects of biographies, criticisms and reviews, or any topic for which the subject entry would be the name of a person or place. It is then called the "name" catalogue.

Subject Catalogue.—This shows what the library contains on any given subjects. For lack of time or money it records in many libraries only books, but a complete catalogue would add pamphlets, articles in periodicals, papers, transactions, essays and collected works, maps and whatever material one studying that topic might want. The Decimal classification, now generally used by libraries, has over 20,000 subject headings and many new ones are added yearly. By means of its very full and simple index, any one who knows what a book is about may readily classify it minutely; the youngest assistant knowing clearly what subject he seeks may find it with equal ease.

The most common form of catalogue extends the name list to include any subject on which the library has a book. A catalogue with authors, titles and subjects in a single alphabet, with cross references from various synonyms so that one consults it like a dictionary, is called a dictionary catalogue. The author catalogue corresponds to the personal list in a directory; the classed catalogue to the business section showing who is engaged in each specific line of business. A dictionary catalogue requires the least explanation and is most popular, but it is more difficult to make well, and except at prohibitive cost cannot give intelligent investigators as clear and methodic exhibits of a library's resources as may be found in the best classed catalogues. Larger libraries have many special catalogues, bibliographies and indexes as keys to their own special collections.

Annotation or evaluation is a most important factor in modern cataloguing. Its purpose is to tell in fewest words what readers are most likely to wish to know about a book as to its scope, treatment and value. The American Library Association publishing board, to which Andrew Carnegie recently made a first gift of \$100,000, is publishing numerous lists on this plan. The New York State Library is preparing with the co-operation of nearly 300 prominent librarians and specialists the annotated A. L. A.

catalogue which the national library will publish for the St. Louis exposition of 1904. New editions constantly revised and with more notes will follow, so that both librarians and readers will have a guide to 8,000 or 10,000 of such of the best books still in print as would be selected as a model library for a small town.

Lending.—A loan system must give the quickest possible service consistent with accurate and complete records. In America the card system is found better than the indicators so largely used in England. The librarian must know where every book is, when it should be returned and must be able to find daily those that are delinquent. Extra privileges in number of books or time retained are given to scholars having special claim, and many libraries allow two books instead of one provided that only one is fiction. Inter-library loans are frequent so that a reader in one library may, when necessary, secure a book to be found only in some other.

Libraries grow more liberal in privileges to readers who now find a large number of the most used books on open shelves instead of having to ask for each book consulted. In many libraries not only so called reference books but thousands of other volumes are thus thrown open to the public. Losses are not large compared with benefits, and the system grows in favor. The recently novel information bureau or reference desk in charge of an expert librarian whose sole function is to answer readers' questions has become a common feature, while the larger libraries are establishing a library faculty, each member taking some special subject on which he will be a recognized authority. Special rooms are set apart for important subjects, each in charge of a specialist. Even the smallest libraries are providing a children's room with low chairs and tables and a sympathetic librarian devoted wholly to their interests. Experience proves that time and money yield larger returns when spent on children than on adults. The children's room becomes the best possible training school for supplying readers who will use the library properly. Rooms for women's exclusive use are little used, women apparently seeing no more occasion for separate provision than in churches, lecture halls or theatres.

Support of libraries by fees is giving way to support by taxation, as a fee is prohibitive to many, and communities are coming to recognize that it is as much for their interests to have the "people's university" as the public schools free to all. Hours of opening have been lengthened from two or three a day till the larger libraries usually open from 8 A.M. to 10 P.M. and no longer close for evenings, holidays, vacations or the annual inventory of books. Sunday opening has proved unexpectedly successful. The theory of the modern library is to be available to readers at any time when they are inclined to use its privileges.

Paid Help.—A highly appreciated accommodation, offered by the New York State and some other libraries, is assistance of an extent or nature not properly provided at public charge, for mere cost of the time spent, estimated at the rate of annual salary. This saves people at a distance costly journeys, because an expert trained in a given library can often find as

LIBRARY BUILDINGS—LIBRARY SCHOOLS

much in an hour as the reader himself would find in a whole day. The telegraph or long distance telephone makes the central cyclopædic libraries quickly available for large areas, and editors, lawyers and others whose time is specially valuable may get needed information, and if wished translations, verified copies or any library service needed quickly at the trifling cost of the time of the lowest salaried assistant competent to do the work.

MELVIL DEWEY,
Director New York State Library.

Library Buildings. See LIBRARY ADMINISTRATION.

Library Schools. With the advance of the free library movement and the growing complexity of the functions and organization of the modern library, the need has been increasingly felt for specially trained librarians. The first library school was organized in 1887 as a department of the work of Columbia College, under the charge of Melvil Dewey, and has since become the New York State Library School. At that time the course consisted almost entirely of instruction in the more technical work of library administration, but since then the ideals and scope of library schools have broadened, and they aim to give their students not only technical courses, but such courses as will enable them to deal with the public successfully, and become a real educational force in the community where they may be placed. The course in library schools usually includes cataloguing, bibliography, shelf-listing and accession work, library building, instruction in printing and book-making, reference and loan work, and general library economy; some schools provide, in addition, courses in history of libraries, and “selection of books”—that is, the critical study of books with a view to determining their fitness for use in different kinds of libraries and with different types of readers. As there are few text-books, the instruction is mostly by lectures and the students’ working out problems, preparing sample catalogues, accession books, etc.; all the schools have also some provision for actual work in a library. Instruction is given in different systems of cataloguing, loaning of books, and other technical work, and both the more complex systems suited for large libraries, and the more simple systems for small libraries are taught; sample blanks, forms, and fittings for all departments are used to illustrate the different methods.

Individual Schools.—The first library school was the New York State Library School, founded as has already been mentioned in connection with Columbia College (now Columbia University). In 1889 when Mr. Dewey, its director,

was appointed State librarian, the school was moved to Albany and became a part of the University of the State of New York. Its curriculum has gradually been enlarged, and its entrance requirements raised until in 1903 it was decided to require a full college course for entrance to the school; the degree of B. L. S. (bachelor of library science), which was at one time given only to those who had attained a certain rank throughout the course, is now given to all graduates who do the full work of the school; a carefully prepared bibliography or reading list on some approved subject is required, in addition to the class and practice work, for this degree. The practice work is provided for in the State library, and the traveling library and home education department. The Pratt Institute Library School was opened in 1890; entrance is by examination only; the main course is for one year, but a second independent course of one year is given in advanced work; separate certificates are given to show completion of work in each course; and those students who complete the two years’ work can take the diploma of the Institute by passing the Institute’s normal examinations. Practice work is required in the Institute library, and may also be had in various settlement libraries and home library work; in 1903 the experiment was tried of having the incoming class do two weeks’ practice work in the library before the regular instruction was begun; this proved successful and will be continued. The Drexel Institute Library School was opened in 1892; entrance to this school is by examination, and a certificate is given on completion of the course. The Illinois State Library School was opened in 1893 at the Armour Institute of Technology, and in 1897 became a part of the State University. The library course proper is two years, before which three years’ collegiate work is required; previous to 1903 only two years’ collegiate work was required. For the completion of the three years’ collegiate and two years’ library work, the degree of B. L. S. is given; for three years’ collegiate and one year’s library work, the degree of A. B. in library science. In addition to the regular library school courses, a special course in the care of public documents is given. Practice work is provided for in the University Library, and in the Champaign Public Library, a branch of the latter being entirely under the charge of the students of the library school. Since the establishment of these four more important schools, library school departments have been added to several universities and colleges. Among these are Department in Library Science in Chicago University, the course in Library Economics in Syracuse University, the School of Library Science in Columbian University, Washington, and the course in Library Science of Simmons College, Boston. Of these the Chicago department requires two years of college work for entrance; Syracuse admits on high school diploma. The Simmons College course (started in 1902) extends over two years, the library school work being done in connection with work in other departments of the college; a third year of advanced work is given to those who have completed their college work and can give their full time to the technical library work. The college library is under the charge of the library school students.

LIBRARY OF CONGRESS — LICH OWL

One other school, devoted to a special line of work, should be mentioned, the Training School for Children's Librarians at the Carnegie Library of Pittsburg. This was started in 1900 as a training class of the library; entrance is by examination or by college diploma, and a certificate is given at the completion of the work. One half the time is given to practice work in the children's room of the library.

Summer Schools.—A number of library summer schools have been organized, mainly with the idea of giving training to those who already hold library positions, or have been appointed to such positions. The instruction is, of course, not so thorough as in the regular library school, but is entirely practical; the courses usually cover the whole range of library science in a general way, and in most summer schools special courses are also given in one or two technical subjects. Among these schools are the Amherst summer school, the Chautauqua school, the New York State Library summer school, the summer library courses of the universities of Missouri and Wisconsin, and the summer schools under the charge of the State library commissions of Indiana, Iowa, and Minnesota.

Besides these schools, many libraries have apprentice classes, designed mainly for instructing and training assistants for such libraries; but a general letter of recommendation to all libraries is in many cases given the graduates of these apprentice classes. Of the larger libraries to have such classes are the public libraries of Providence, R. I., Brooklyn, New York City, Madison, Wis., and Nashville, Tenn. Lately also several colleges have introduced courses in bibliography and the history of printing, and some normal schools have similar courses, including something also of general library economy. This is not with the purpose of training the students to become librarians, but with the idea of enabling them to make the best use of the resources of the library, and, in the case of normal graduates, to enable them to organize school libraries and co-operate intelligently with the public library work.

Consult: The catalogues and reports of the individual schools; 'The Library Journal,' for July, 1898 (Conference number), and for July, 1903 (Conference number).

Libration, in astronomy, an apparent oscillatory motion of the moon, which causes parts near the edge to appear and disappear from time to time. It was discovered by Galileo. If the moon moved round the earth with a uniform angular velocity equal to its angular velocity of rotation on its axis, and if its axis were at right angles to its orbit, the same side of it would always be presented to the earth, and we should see only one-half of its surface; its libration enables us to see about 4-7ths of its surface. The moon's orbital angular velocity is sometimes slightly greater and sometimes slightly less than its axial angular velocity, hence equatorial parts of the moon near the edge are sometimes visible and sometimes out of sight. There is also a very small diurnal libration due to the motion of an observer on the earth.

Libri-Carrucci della Sommaia, Guillaume

Brutus Icile Timoléon, gē-yōm broo-tüs ē-sēl tē-mō-lā-ōn lē-brē kā-roo'chē dē'lā sōm-mä'-yā, COUNT, French mathematician: b. Florence, Italy, 2 Jan. 1803; d. near Fiesole, Italy, 28 Sept. 1869. His father was an Italian adventurer, in 1816 condemned at Lyons to ten years' imprisonment at hard labor and to branding for counterfeiting goods, and who finally became a secret agent of the king of the Netherlands. The son became professor at the University of Pisa, where he published in the scientific journals several articles on the theory of numbers, on analysis, and the resolution of indeterminate equations of the first degree. Having been compromised by his political views, he fled in 1830 to France, where the friendship of Arago introduced him to the world of science. Naturalized in 1833 as a Frenchman he was called to the Academy of Sciences as successor of Legendre. He became inspector-general of public instruction, obtained the cross of the Legion of Honor, and was appointed inspector-general of the libraries of France, an office created expressly for him. Several works published by him during this period gave him a widely extended reputation. Among these were 'Histoire des Sciences Mathématiques en Italie depuis la Renaissance jusqu'à la Fin du 17e Siècle' (1838-41); 'Souvenirs de la Jeunesse de Napoléon' (1842); and 'Lettres sur le Clergé et la Liberté de l'Enseignement' (1844). During the latter part of the reign of Louis Philippe, he was suspected of having made use of his office of inspector-general of libraries to plunder them extensively. After the minutest investigation, Libri, who had escaped to London, was found guilty and condemned in June 1850, to ten years' imprisonment and degradation from public employment. A remarkable paper was written on his behalf by Paul Mérimée entitled 'Le procès Libri,' and published in 1852 in the 'Revue des Deux Mondes.'

Liburnia, li-bér'ni-a, in ancient geography, a district of Illyricum along the coast of the Adriatic, now included partly in Croatia and partly in Dalmatia. The country is mountainous, and the inhabitants were celebrated from early times as sailors. They occupied the northern islands of the Adriatic, and had settlements on the Italian coast. Their chief towns were Scardona and Iader.

Libya, lib'i-a, the geographical term of the ancients for Africa. At first it had mythical boundaries. Though Herodotus seems to have known that Africa was a peninsula, the moderns knew little about this till the Portuguese doubled the Cape of Good Hope in 1497. Homer and Hesiod comprised under Libya all the territory west of Middle and Lower Egypt. The Macedonian kings of Egypt, on the development of commerce, necessarily acquired a more exact knowledge and the wars of Rome with Carthage first gave men accurate knowledge of the interior. The sandy tract in which the Sahara is included was called the Libyan Desert and that portion of the Mediterranean extending between the coast of Africa and Crete was known as the Libyan Sea. See AFRICA.

Lich Owl, or Litch Owl (Germ. *leich*, a corpse, O. E. *lich* or *lych*, dead), a provincial British name for any owl, which screams at

LICHENS

night, and is superstitiously regarded as portending death. From the earliest ages the hoot of the owl has been regarded as ominous. Ovid, Virgil, and Shakespeare contain many illustrations of this common superstition. See LYCH-GATE.

Lichens, li-kĕnz or lich'ĕnz (Lat. *lichen*, Gr. λειχήν), a large but artificial group of the higher fungi (*Carpophyta*), characterized by parasitic growth upon the lower blue-green and yellow-green algae (*Protophyta*, *Chlorophyceæ*). Lichens are of the widest occurrence in nature, appearing as gray, yellow, and brown crusts or masses almost everywhere upon trees, rocks and soil. The number of genera and species differs more or less with the authority cited: the valid genera number not far from 250, while the species are in the neighborhood of 4,000.

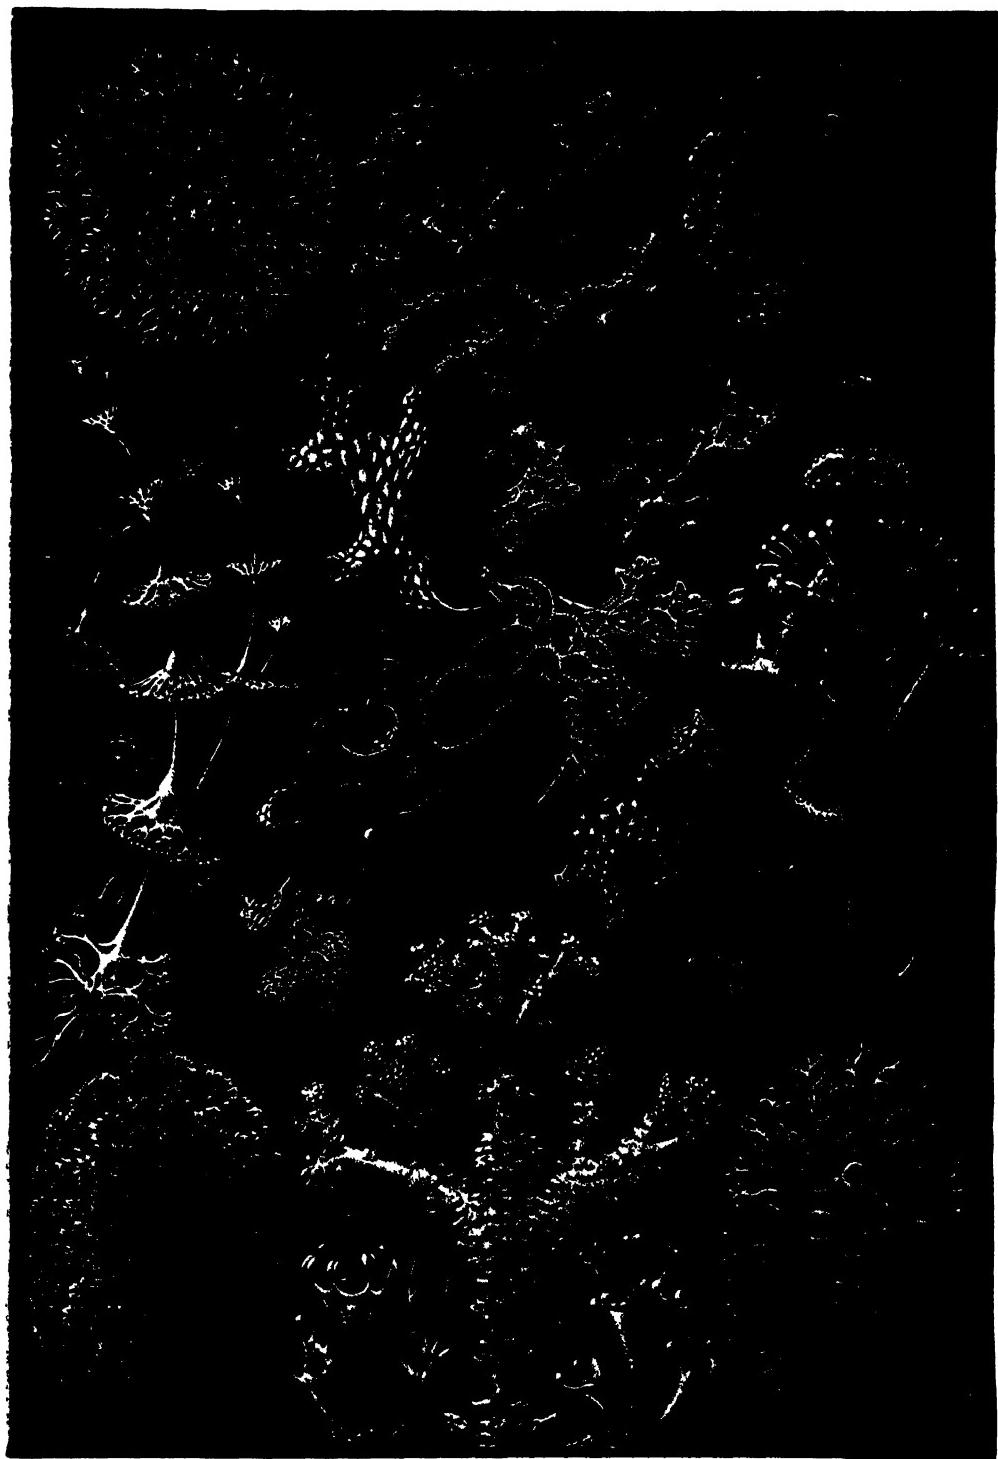

The vegetative body or thallus varies from a fraction of a millimetre to several decimetres in size, though it shows relatively little variation in thickness. In texture it is powdery, leathery, paper-like, or, in the case of many forms with blue-green algae, gelatinous: the prevailing colors are gray, brown and yellow, while green and black sometimes occur. The shape of the thallus is typically orbicular or stellate; it is often irregular, especially in branched forms. In general appearance, the thallus varies within wide limits; as a rule, however, three types, crustose, foliose and fruticose, may be clearly distinguished. The crustose type is the primitive one, showing in its granular, warty, and areolate forms the various stages through which the thallus has passed in its development from the original mycelium. The crustose thallus is so closely in contact with its substratum that it cannot be separated from it without tearing. The foliose type is a higher development of the crustose. It is usually a definite, leaf-like structure, more or less lobed at the margin and attached to the stratum somewhat loosely or at but a single point. The fruticose type is a special modification of the foliose, in which the latter is more or less flattened or cylindrical and erect or pendulous. This form is probably an adjustment to conditions of diffuse light. It is especially characteristic of tree-lichens, and of certain ground forms, such as *Cladonia*, where it is termed the podetium. In the latter, there is also developed an accessory or secondary thallus, consisting of minute, leaf-like scales.

The simplest thallus consists merely of a few fungus threads enclosing the irregularly disposed cells of the host or alga. Ordinarily, however, the algal cells not only have a definite position, but the fungal portion of the thallus is likewise highly specialized. Naturally, this differentiation is least in the crustose forms and greatest in the fruticose ones. The structure of the foliose type may be taken as fairly representative, except of the gelatinous lichens, in which the algae are scattered throughout the thallus. A definite epidermal layer is wanting except in a few of the higher lichens, where the outer filaments have been gelatinized, resulting in the formation of a structure closely resembling a cuticle. As a rule, however, the uppermost part of the thallus is the cortical layer. This consists of hyphae (filaments) compacted in

such a way as to produce a tissue which looks much like parenchyma and is called in consequence, pseudoparenchyma. The function of the cortical layer is in part mechanical or supportive and in part protective. Its structure seems to depend primarily upon the latter function: it is least in those forms growing in forests, and greatest in those found in the open. Below the cortical layer and continuous with it is found the host or algal layer, consisting of filaments more or less loosely intertwined with the algae. This is the nutritive layer, in which the fungal hyphae draw their nourishment from the host-cells. The connection between the two may be merely by contact or by penetration. In the latter case the fungal hyphae either penetrate the protoplasm of the host and finally destroy it, or merely pierce the cell-membrane and lie in contact with the protoplasm. In either event, the hyphae develop special branches for contact or penetration, which are called haustoria. The algal layer is a specialized portion of the medulla which lies just below it. The hyphae of the two layers are continuous, but they do not develop haustoria in the medulla, where they tend also to run more or less parallel with the direction of growth. The medullary layer primarily serves the function of transport; it is likewise used for the storage of lichenin (lichen-starch) and fats. The lower surface of the thallus is covered with a cortical layer similar in structure to that of the upper surface. Generally, however, it is somewhat thinner and is designed rather for absorption than for protection. It is frequently produced into fascicles of hyphae termed rhizoids and cilia.

The thallus of many lichens exhibits several peculiar structures, which are the direct result of the symbiosis of fungus and alga. The most frequent and most important of these is the soredium. This is a minute irregular mass of fungal hyphae and algal cells, readily carried by wind or water, and able to grow directly into a lichen thallus under the proper conditions of moisture and warmth. Soredia occur upon the upper face of the thallus of many lichens as elevated powdery masses or tubercles. They arise in the algal layer of the thallus by the repeated branching of a fungal filament in such fashion as to completely enclose one or more cells of the alga, which also increase in number. The hyphae become more or less gelatinized and compacted into a surface very resistant to desiccation. The soredia are pushed upward through the thallus by the growth of the filaments below, and are finally extruded through a rift in the cortical layer, constituting a sorus. Normally, the soredia are carried away from the sorus and develop independently, but in some cases they grow while still in contact with the mother-thallus, producing minute, leaf-like scales upon the latter. These are the so-called isidiod growths or phylloclades, found in *Usnea* and related genera. Soralia are structures which arise from the medulla or even from the lowermost layer by the upgrowth of a mass of parallel filaments which penetrate the algal layer and there develop into normal soredia. Cephalodia bear the general appearance of soredia, but in origin and function they are quite different. They are distinguished as external, and internal. The cause of their development is unknown:

LICHENS.

1. *Parmelia stellaris*.
2. *Cladonia retipora*.
3. *Parmelia olivacea*.
4. *Cladonia perfoliata*.

5. *Sticta pulmonaria*.
6. *Cladonia verticillata*.
7. *Parmelia caperata*.

8. *Cladonia squamosa* (center), *C. fimbriata* (left), *C. cornucopiæ* (right)
9. *Hagenia crinalis*.

LICHENS

they are said to arise from the soredia of other lichens, which have lodged upon the thallus. They have never been produced experimentally, however, and it seems much more probable that they are modifications of the thallus due to a change in the life form of the algal element. The cyphellæ are flat or concave gaps in the lower cortical layer of the thallus of *Sticta* and *Stictina*. They are filled with variously branched hyphae of the medullary layer and probably function as organs of absorption and respiration. The spermagonia are minute black dots occurring on the upper face of many lichens, especially near the margin of the thallus. Structurally they are identical with those propagative organs of black fungi that are termed pycnidia. They are spherical bodies with a membranous or carbonaceous envelope, containing a layer of rod-like filaments which bear at their tips tiny spore-like bodies called spermatia. As the names indicate, the spermagonia were supposed to be male reproductive organs, and the spermatia the fertilizing cells. There now seems to be little doubt, however, that they are propagative organs or pycnidia inherited from fungus ancestors. In a few cases they may be pycnidial parasites, such as *Phyllosticta*.

The fruit (sporocarp) of those lichens which bear spore-sacs (ascolichens) is called a peritheium when the fungus is one of the black fungi (*Pyrenomyctcales*), a hysterothecium, when it belongs to the cleft fungi (*Hysteriales*), and an apothecium when the lichen is a cup fungus (*Discomyctcales*). All these agree essentially in structure, though they differ in form: the peritheium is globoid, opening by a minute pore at the top, the hysterothecium, linear or irregular, opening by a cleft, and the apothecium usually open and disk-shaped. The essential parts in each are the same, namely; spore-sacs (asci), the spores, and the sterile threads (paraphyses). The apothecium is the highest type of spore-fruit and the most widely distributed. It consists usually of the following parts: the thecium, the central portion consisting of the asci, sometimes called thekæ, and the paraphyses; the epithecium, which lies above the asci; and the hypothecium which is found below them. The latter often extends around the sides of the thecium also, and is there termed the excipie (proper excipie, parathecium). All of these consist of densely compacted elongate hyphae (prosenchyma) which are without algae and are often more or less dark colored. In most of the higher lichens, the excipie is surrounded by the tissue of the algal layer, producing a thalline margin (thalline excipie) about the apothecium. The apothecium usually sits directly upon the thallus; occasionally it is stalked, and less frequently it is immersed or innate. Lichens show the same differences with respect to paraphyses, asci and spores that are to be found among the other cup-fungi and black fungi. The paraphyses are simple or repeatedly branched, continuous or septate, gelatinized or non-gelatinized, persistent or evanescent. They are often compacted and dark-colored at the tip, appearing to be continuous with the epithecium. The spore-sacs of lichens are cylindrical or clavate in form, more rarely obovoid. Their walls are thin, though sometimes gelatinized; they do not react to iodine as a rule, except when very young. The ascii

usually open by a terminal slit; in a few cases the entire wall breaks away. The number of spores in an ascus varies from one (*Pertusaria*) to many (*Acarospora*); the normal number is eight, six or four. The arrangement of the spores is usually irregular, though they are sometimes in one row (monostichous), or in two rows (distichous). Lichen spores are ordinarily colorless and simple, less frequently dark brown and many-celled. They may be two-celled (bilocular), several-celled (plurilocular), or muriform, when the partitions run in both directions. The wall of the spore is smooth and without appendages; the contents may be hyaline, granular or guttulate.

Physiology and Reproduction.—The functions of lichens are essentially those involved in the relation between parasite and host, modified to an important degree in those forms with well-developed thallus. Absorption of water takes place readily upon both surfaces of the thallus, but especially on the under side, where hyphae, cilia and rhizoids all act more or less efficiently as absorptive agents. According to Zukal, the hyphal hairs are capable also of absorbing moisture directly from the air, in *Physcia*, *Peltigera*, *Sticta*, etc. Water-storage takes place in the algal and medullary layers. It is effected primarily by the algal membranes, especially of the blue-green slimes, and to a degree also by the lichenin of the hyphae. Zukal has suggested that the cephalodia, because of their blue-green algae, are probably to be regarded as structures for the storage of water. The ability of the lichen thallus to retain water arises from its complexity, and from the presence of the gelatinized cortex. Lichens exhibit a number of somewhat primitive devices for the exchange of gases. These are often mere rifts in the thallus, or degenerate pycnidia; sometimes definite openings are present, or absorption takes place through loose protuberances. A specialized organ for this purpose is found in the cyphellæ of *Sticta* and *Stictina*, which are primitive breathing pores, making direct connection between the air and the medullary layer. The latter serves as a pathway for the transport of water and gases to the various parts of the thallus.

The relation of the lichen thallus to the environment is obscure. Of all macroscopic plants, lichens resist drying-out the most successfully. With respect to the temperature extremes which they can endure, they are surpassed only by the bacteria. Many lichens withstand temperatures greater than 65° C., and nearly all are able to resist the intense cold of arctic and alpine winters, with minima of -40° to -60° C. Lichens exhibit very different sensibility to light: the majority of them grow in the fullest sunlight, while some, *Evernia*, *Usnea*, *Peltigera*, *Graphis*, etc., are adapted to more or less intense shade. In alpine regions especially, orange and yellow thalli occur almost exclusively on the under, or shaded, side of rocks. This fact is explained by Zukal's researches, in which he found that the algal layer was most highly developed under a cortex orange or yellow in color, these colors being most penetrable by the rays active in carbon assimilation. The color of the cortex is also thought to be a protection against excessive illumination, though this explanation can scarcely hold for those

LICHENS

lichens in which the lower cortex is highly colored. According to Schwendener, the growth of the thallus is largely intercalary, marginal or apical growth being relatively insignificant. In lichens with yellow-green algae, the growth of the thallus is determined by the fungus, and the development of the algal layer takes place subsequently. In this process, the algae and hyphae show a tendency to aggregate into tubercles, which modify the surface of the thallus. Somewhat similar sculpturings are produced by tensions in the growing thallus, especially by the alternation of wet and dry periods. In nearly all of the gelatinous lichens, and particularly those parasitic on filamentous algae, growth is controlled by the alga, and the fungus has little or no influence upon it.

The propagation of lichens occurs ordinarily by means of soredia. It may take place also by fragments of the thallus, whether abstracted naturally or cut off by accident. The propagative value of the pycnidium (spermogonium) in nature is unknown. The conidia have been germinated in cultures with difficulty, and at present there is no evidence that they grow more readily under normal conditions. Reproduction is a characteristic feature of the lichens: a few species produce apothecia rarely, while in certain sterile forms they are never developed. It is still an open question whether the apothecium is the result of fertilization. Some investigators have thought to demonstrate the presence of a carpogone and trichogyne, and to follow the development of a spore fruit, which results from the contact of spermatium and trichogyne. The germination of many spermatia points strongly to the conclusion that these are mere conidia and not male sexual cells. No fusion of sexual cells has yet been seen in lichens, and, until this is seen, it is impossible to settle the question of their sexual nature. The apothecium arises usually from certain more or less distinctly twisted hyphae lying between the medulla and the algal layer. Sometimes the point of origin is just beneath the cortex, especially near the margin, and in crustose forms it is in the hyphal layer just above the substratum. The development is essentially the same as in the other cup-fungi; the hyphal fundament increases in size, and becomes differentiated above into two sorts of threads. The first to grow up are the paraphyses, in the centre of which push up the club-shaped branches, which become the ascii. Spore formation in the ascus follows the method typical of all sac-fungi. The escape of the spores takes place through a terminal rift in the ascus or by the breaking up of the latter. The mature spores germinate readily under the proper conditions, usually sending out a single filament from each cell; large spores, however, such as those found in *Megalospora* and *Pertusaria*, produce many germinating filaments. The young mycelium is capable of slight development only, unless it comes in contact with the proper alga, when it grows at once into the thallus. The uncertainty that the spores will germinate in a place where the proper host occurs makes multiplication by spores much less sure than by soredia. In a few cases (*Endocarpon*, *Staurothele*, etc.), this disadvantage has been overcome by the development of algae in the thecium between the paraphyses and spore-sacs (hymenial gonidia).

These are ejected with the spores, and, clinging to the latter, furnish a certain substratum for the germination of the spores.

Origin and Classification.—Lichens are sac-fungi and rod-fungi which show more or less similarity in their vegetative body because of their parasitism upon certain algae. The clew to their origin and relationship is to be found in the inherited reproductive organ, the sporocarp, and not in the thallus. From this standpoint, the group is highly artificial, containing representatives of two distinct classes of fungi, the *Ascomycetes* and the *Basidiomycetes*. The absidiolichens are a small group, containing but a few genera: the ascolichens consist of the representatives of several unrelated families. It is evident that the lichens have not arisen from a single point, as members or offshoots of one line of development, but that they have originated at several widely separated points. They are of multiple origin; that is, they are polyphyletic. In ascolichens, the form of the sporocarp indicates the main places of origin; the *Verrucariaceæ*, with perithecia, are *Pyrenomycetales*; the *Graphidaceæ*, which show the hysterothecium, belong to the *Hysteriales*; the remaining families, *Caliciaceæ*, *Collemaceæ*, *Parmeliaceæ*, etc., belong to the *Pezizales*.

The following synopsis will indicate the relationship and limits of the various families of lichens:

Class Ascomyceteæ: fruit a sporocarp, spores borne in sacs (asci).

Order Pyrenomycetales: sporocarp a peritheciun.

Family Sphaeriaceæ: mycelium filamentous, saprophytic or parasitic on tissues.

Family Verrucariaceæ: mycelium thalloid, parasitic on yellow-green algae.

Order Hysteriales: sporocarp a hysterothecium.

Family Hysteriaceæ: mycelium filamentous, hysterothecium carbonaceous.

Family Hypodermataceæ: mycelium filamentous, hysterothecium membranaceous.

Family Graphidaceæ: mycelium thalloid, on algae, hysterothecium membranaceous or carbonaceous.

Order Pezizales: sporocarp an apothecium.

Apothecia and thallus leathery, waxy or carbonaceous, never gelatinous.

Family Patellariaceæ: mycelium filamentous, mostly saprophytic.

Family Lecidiaceæ: mycelium thalloid, apothecium sessile, exciple without algae (proper).

Family Cladoniaceæ: mycelium thalloid of two sorts, primary and secondary; apothecia borne on stalks (podetia), proper exciple.

Family Parmeliaceæ: mycelium thalloid, algae yellow-green, exciple with algae (thalline).

Family Pannariaceæ: mycelium thalloid, algae blue-green, proper exciple.

Apothecia and mycelium gelatinous.

Family Bulgariaceæ: mycelium filamentous.

Family Collemaceæ: mycelium thalloid, on blue-green algae.

Class Basidiomyceteæ: fruit a hymenophore, spores borne on stalks (basidia).

Order Hymenomycetales: hymenophore exposed on a pileus.

Family Thelephoraceæ: hymenophore smooth, mycelium filamentous or thalloid (in *Cora*, *Rhipidonema*, *Dictyonema* and *Laudatea*).

LICHFIELD — LICINIUS

Order Gasteromycetales: hymenophore enclosed in a peridium.

Family Sclerodermataceæ: peridium broad sub sessile, gleba excavate, mycelium filamentous, or thalloid in *Emericella*.

Distribution and Role.—Lichens are distributed over the entire earth: they are least numerous in the tropics and reach their maximum development in alpine and polar lands, where they often form the principal vegetation over immense stretches. Many species are widespread, especially in the northern hemisphere: some of these, such as *Cladonia rangiferina*, *Urzecularia scruposa*, *Usnea barbata*, etc., are truly cosmopolitan. In the tropical and temperate zones, the greatest wealth of lichens is found upon bark and wood. In alpine and polar regions, the stone and earth forms are predominant. In these places, lichens play their most important part in the economy of nature. They take the initiative in the disintegration of the hardest rock by virtue of the acids secreted by the thallus; they are likewise very effective in binding together the new soils which result in this way and in contributing organic material by their decay. In all rocky habitats they are the pioneers which prepare the way for the appearance of more highly organized plants, mosses, grasses, etc. In the case of tree-lichens, the tree is not affected by the lichen, except in so far as the bark may be ruptured by it mechanically. It is a question whether lichens exert any really injurious effect upon timber, though they probably hasten the decay of boards, posts, etc., by increasing the amount of moisture present.

A few lichens are of value as food. The most important among these is the so-called "reindeer" moss, *Cladonia rangiferina*, which covers vast stretches in the north and constitutes an invaluable supply of food for the reindeer and caribou. In Japan, *Gyrophora esculenta*, which is collected in abundance in the mountains, is of sufficient importance to be an article of export. The arid regions in northern Africa and western Asia produce large quantities of the manna-lichen, which is used to make bread, especially by the Tartars. This lichen is readily torn away from the substratum by the wind and is carried often to considerable distance before falling as "manna rain." This phenomenon has been observed repeatedly in modern times, and probably accounts for the manna of the Israelites. "Trip-de-roche" is an edible *Umbilicaria* of arctic America, but the presence of the bitter principle so common in lichens restricts its use as a food. Lichens owe their food value almost wholly to their high content of lichenin, or lichen-starch. Lichens, though once of extensive application in dyeing and in medicine, have fallen almost completely into disuse in both. The various kinds of orseille, which were made from *Roccella tinctoria* and held in high esteem for their brilliant purples, have been entirely replaced by the aniline dyes. Litmus, which is a similar dye made from a species of *Lecanora*, is still extensively used in chemistry because of its red coloration in the presence of an acid. "Iceland moss," *Cetraria islandica*, is still used officially: it contains cetrarin, a bitter principle which is tonic and astringent, and a large amount of lichenin.

A., 'A Text-book of General Lichenology' (1897); Schneider, A., 'Guide to the Study of Lichens' (1898). FREDERIC E. CLEMENTS,
University of Nebraska.

Lichfield, lich'fēld, England, an episcopal city of Staffordshire, 17 miles southeast of Staffordshire. The principal edifice is the cathedral, a noble structure of early English and transitional architecture with a richly decorated west front, and three spires—two on the west, each 180, and one in the centre 280 feet high. The see of Lichfield was founded in 656. The city has interesting literary associations, Johnson, Addison, and Garrick, born in the town or neighborhood, having been educated at the old grammar school. Pop. (1901) 7,902.

Lichtenberg, Georg Christoph, gā-ōrg' kris'tōf lih'ten-bērg, German satirical writer and physicist: b. near Darmstadt 1 July 1742; d. Göttingen 24 Feb. 1799. He was educated at the University of Göttingen and became professor there in 1767. During frequent visits to England he collected material for his explanations of Hogarth whom he thus assisted to popularize in Germany. He gained great celebrity as a lecturer on physical science. His being a hunchback may very possibly have embittered a naturally satiric disposition. The best of his satires are those on the notorious literary pirate Tobias Göbhard; the essay on 'The German Novel'; 'Timorus,' ridiculing Lavater's zeal for proselytizing; and 'Pronunciation of the Wethers of Ancient Greece,' aimed at Voss's system of pronouncing Greek. His brilliant sayings have been collected and published in a separate volume, 'Lichtenberg's Thoughts and Maxims: Light Rays from his Works' (1871).

Lichtenberg, Leopold, American musician: b. San Francisco, Cal., 22 Nov. 1861. In early childhood he showed his fondness for the violin and received careful training. In his 12th year was asked by Henri Wieniawski, then on a visit to California, to become his pupil, and accordingly spent three years at Brussels Conservatory. Fresh from his European successes, he was engaged in Theodore Thomas' orchestra and then spent three years more abroad playing in the chief cities. On his return to America he became a member of the Boston Symphony Orchestra and later was appointed head of the violin classes at the National Conservatory of Music, New York.

Licinius, li-sin'i-üs, Caius, Roman tribune. He came of a plebeian family, but rose to the rank of tribune, receiving the surname of Stolo, or Useless Sprout, by reason of the law which he established forbidding any one to possess more than 500 acres of land. His reason for this was that when more land was cultivated by any one owner the latter could not pull up the useless shoots (*stolones*) which grew from the roots of trees. Another law of his enactment allowed the plebeians to share the consular dignity with the patricians; and he himself became one of the first plebeian consuls, 364 B.C.

Licinius, Caius Flavius, Roman emperor: b. Dacia about 270; d. 324. He was made Augustus by the emperor in 307, and became emperor of Rome after the death of Galerius about 312. He was defeated by his brother-in-law, Constantine, 323, and put to death the year following. His son, Flavius Valerius, de-

LICK—LICK OBSERVATORY

clared Cæsar in 317, was slain at Constantinople in 326.

Lick, James, American philanthropist: b. Fredericksburg, Lebanon County, Pa., 25 Aug. 1796; d. San Francisco, Cal., 1 Oct. 1876. In 1821 he set up in the pianoforte business at New York, and later was a manufacturer of musical instruments at Buenos Ayres, Philadelphia, Valparaíso, and elsewhere. In 1847 he went to California, where he gained wealth through investments in real estate and various enterprises. In 1874 he placed \$3,000,000 at the disposal of seven trustees, by whom they were to be applied to specified uses. The principal divisions of the funds were: To the University of California, for the construction of an observatory and the placing therein of a telescope to be more powerful than any other in existence, \$700,000 (see LICK OBSERVATORY); for the building and maintenance of free public baths in San Francisco, \$150,000; to found and endow an institution of San Francisco to be known as the California School of Mechanic Arts, \$540,000; for the erection of three appropriate groups of bronze statuary to represent three periods in Californian history and to be placed before the city-hall of San Francisco, \$100,000; to erect in Golden Gate park, San Francisco, a memorial to F. S. Key, author of 'The Star-Spangled Banner', \$60,000.

Lick Observatory, astronomical department of the University of California. James Lick (q.v.), by deeds made in 1874 and 1875, charged a board of trustees to expend the sum of \$700,000 for the purpose of purchasing land and constructing "a telescope superior to and more powerful than any telescope yet made . . . and also a suitable observatory . . . to be made useful in promoting science." Under the provisions of this deed a site was selected in 1876 on the summit of Mount Hamilton about 26 miles, by road, from San José, Cal. The land (about 3,000 acres) was granted at various times by the United States and by the State of California.

Astronomical observations of precision and delicacy require a steady atmosphere as well as a very transparent one, and the site chosen is favorable in both respects. This was thoroughly tested in 1879 by Prof. S. W. Burnham before any buildings were erected. The first board of trustees (D. O. Mills, president) chose as chief advisers Profs. Simon Newcomb and Edward S. Holden, and appointed Prof. Holden as director. In October 1874 the latter submitted a plan for the building of the observatory and a programme of work, which were accepted by the trustees, according to which the buildings were constructed and the work carried on from 1874 to 1897. The County of Santa Clara built a fine mountain road to the summit, in 1876, at a cost of \$78,000. The work of construction was begun in 1880 by the third board of trustees (Capt. R. S. Floyd, president) with Thomas Fraser as superintendent. To obtain a level platform for the observatory 70,000 tons of rock were blasted from the summit. The instruments were ordered from specifications by Dr. Holden, except the object-glass of the great telescope. After a series of experiments Prof. Newcomb advised the construction of a refracting telescope for the main instrument of the observatory. The

glass disks were founded by Feil & Mantois of Paris and figured by Alvan G. Clark. The finished objective is 36 inches in diameter, and has a focal length of 56 feet 2 inches. Besides the visual objective, there is a third lens of 33 inches aperture. When this is placed in front of the visual objective the combination becomes a photographic object-glass of 570 inches focal length (the diameter of the photographic image of the moon is about 5.2 inches). The cost of the visual objective was \$50,000, of the photographic corrector about \$13,000, and of the mounting of the telescope about \$45,000. The cost of the dome complete was about \$85,000; of the whole observatory about \$610,000. The mounting of the great telescope was made by Warner & Swasey, of Cleveland. The whole weight of iron pier and mounting is about 37 tons. The moving parts of the latter weigh about 7 tons; the tube weighs nearly three tons. The telescope is used for visual purposes, and micrometer measurements; it is also used for photographic and for spectroscopic observations. Its steel dome is 75 feet in diameter, and weighs 100 tons. It was built by the Union Iron Works of San Francisco. The floor of the dome is movable vertically (about 16½ feet), according to a plan by Sir Howard Grubb, which ensures a convenient position for the observer, no matter whether the telescope is pointing horizontally or vertically. Other instruments are a 12-inch and a 6-inch refractor, a 4-inch comet-seeker, a 6-inch meridian-circle, a 5-inch photographic telescope, a 4-inch transit, a 5-inch photoheliograph, etc.

The great telescope has been in constant use since its erection, and its optical quality has been proved to be excellent. The admirable design and construction of its mounting and dome have much facilitated its work. In 1895 Edward Crossley, M. P., of Halifax, England, presented to the observatory his 3-foot reflector, which has been a powerful auxiliary to the great refractor. The observatory constitutes the Lick Astronomical Department of the University of California. The directors of the observatory have been: Edward S. Holden (1874 and 1885-97); James E. Keeler (1898-1900); W. W. Campbell (1900—). Its staff has comprised many noted observers: Messrs. Burnham, Barnard, Schaeberle, Tucker, Perrine, Hussey, Aitken, Wright and others. In 1888 the staff was composed of the director, four astronomers, and one assistant. The staff of the observatory in 1903 consists of the director, 3 astronomers, 2 assistant astronomers, 4 assistants, 3 fellows, 1 secretary.

The observatory was one of the very first to be located on a site specially chosen for its adaptation to astronomical work, and its success has had an important effect upon the science of practical astronomy. No one would now think of locating a great observatory without careful consideration of the site to be occupied. The mountain observatories of the world owe much to the experiments made at Mount Hamilton.

The principal objects of research have been: The visual and photographic observation of planets and satellites; the fifth satellite of Jupiter was discovered here by Barnard in 1892. A systematic search for comets has been kept up and 14 unexpected comets have been discovered—Barnard (3), Perrine (9), Coddington

LICKING—LIDDELL

(1), besides a comet discovered by Schaeberle during his observations of the solar eclipse in Chile. Many periodic comets have also been detected and observed. The orbits of new comets have always been promptly computed at the observatory and ephemerides sent out to other stations. Four asteroids were discovered by Coddington in 1898-9. Meteors have been observed and photographed, and their orbits calculated. Double stars have been assiduously observed and many new discoveries made by Burnham, Hussey and Aitken; the orbits of a considerable number of binaries have been calculated. Observations of the zodiacal light and of the aurora have been made by Barnard and others. Successful expeditions have been sent to observe all total solar eclipses since 1888, and very much has been added to our knowledge of solar physics in this way. The transit of Venus of 1882 and three transits of Mercury have been observed and photographed here. The positions of a large number of fixed stars have been determined with great precision by Tucker. Many photographs of the sun and moon have been made. The negatives of the moon have been utilized in the preparation of an atlas of the moon (scale 10 feet to the moon's diameter) by Prof. Weinek, and on a scale of three feet by Messrs. Holden and Colton. A great number of important photographs of the milky way were made here by Professor Barnard and others, and of comets and nebulae by Keeler, Hussey, Perrine and others. A complete outfit of seismometers, for recording the intensity of earthquake shocks was installed at the observatory in 1888, and it was supplemented by similar instruments at Berkeley and at other points in California and Nevada, which regularly report to Mount Hamilton. In this way the elements for a seismometric record for the State were collected and regularly published. At the same time a list of all recorded shocks on the Pacific coast since 1769 was compiled and discussed by Dr. Holden. Spectroscopic observations of nebulae, new stars, comets, stars and planets have been made in great number and with previously unattained precision by Messrs. Keeler, Campbell, Wright, Perrine and others.

The chief problem of the great telescope is to determine the motion of the solar system by spectroscopic observations. The photography of stellar spectra was proposed in the plan of 1874 and attacked in 1888, and it has been followed with marked success, especially in the hands of Prof. Campbell. Since 1896 more than 2,000 negatives of stellar spectra have been secured. A preliminary discussion by Campbell leads to the result that the solar system is moving toward a point in 277° R. A. and 20° N. D., at a speed of 19.89 kilometers (12.35 miles) per second. An expedition was sent (at the cost of D. O. Mills) to the Southern hemisphere in 1903 to extend this research to Southern stars.

The observatory publishes a series of octavo 'Contributions' (No. 1 in 1889, No. 5 in 1895), of quarto 'Publications' (Vol. I. in 1887, VI. in 1903) and a quarto 'Bulletin' since 1901—a journal. The Astronomical Society of the Pacific founded by Prof. Holden in 1889, has close relations with the observatory, and has printed 15 octavo volumes. Visitors are freely admitted to the observatory in the day time to the number of 5,000 or more annually. On Saturday evenings visitors are admitted to look through

the telescopes, and as many as 150 to 200 are frequently registered. In this way the observatory has rendered important services to popular education. EDWARD S. HOLDEN, Librarian U. S. Military Academy, West Point.

Lick'ing, (1) a river of Kentucky, rising in Floyd County, among the Cumberland Mountains, and, after a course of about 200 miles, falling into the Ohio at Newport, opposite Cincinnati. (2) A river of Ohio, the former Indian Pataskala, rising near the centre of the State, and, after a course of 80 miles, flowing into the Muskingum near Zanesville. It furnishes valuable water power.

Lic'orice, or Liquorice, a genus of perennial plants (*Glycyrrhiza*) of the order *Leguminosæ*. About a dozen widely dispersed species are recognized, of which *G. glabra* is the most important, since it furnishes the licorice of commerce. It is characterized by long rootstocks, odd-pinnate leaves, and racemes of separated flowers of various colors, usually pale violet. The plant is a native of southern Europe and western Asia, and is cultivated in Spain, Italy, Russia, and some other countries of the old world, the best grades coming from the first two countries mentioned. The roots and the extracted sweetish principle, of which about \$500,000 worth are imported into the United States annually, are used in making plug tobacco and porter, to flavor cooling drinks, and by druggists to disguise the unpleasant taste of some drugs. Attempts to cultivate the plant in Louisiana and California has proved partially successful, but the crop is not profitable, since three to four years must elapse before it can be dug, and the selling price is small. Cuttings of the rootstock are planted about three feet apart, and when established the plants are allowed to shift for themselves until harvest, when the land is plowed and the rootstocks pulled by hand. No further planting is necessary, since the bits of root left will restock the land.

Lic'tors, in ancient Rome, a name given to those public servants who attended upon the chief magistrates to fulfil their commands, bearing axes tied up in bundles of rods, which were called *fascæ*. When a magistrate of high rank appeared in public the lictors preceded him in a file, following each other. It was their duty to clear the road of the populace. The dictators were preceded by 24 lictors; the consuls, decemvirs, and military tribunes, by 12; the provincial *prætors*, master of the horse, and *proprætors*, by six; and the *quæstors* by five.

Liddell, lid'el, Henry George, English Greek scholar and Anglican clergyman: b. 6 Feb. 1811; d. Ascot, Berkshire, 18 Jan. 1898. He was educated at the Charterhouse and Christ Church, Oxford; took priest's orders in 1838; and for some years lived in Oxford as a tutor of Christ Church. He took no part in the theological controversies which stirred the Oxford of his time, but worked steadily with R. A. Scott of Balliol, afterward Dean of Rochester, at the 'Greek Lexicon' — the well-known 'Liddell and Scott' of successive generations of students — which forms his chief title to remembrance. It first appeared in 1843, but has undergone extensive revision and enlargement in subsequent editions, of which the 8th appeared in 1897. In 1846 Liddell was appointed the head-master of Westminster School,

LIDDON—LIEBER

and in 1855 became dean of Christ Church. He held the deanery till his retirement to Ascot in 1891, and during his rule many salutary changes were introduced. Besides the 'Lexicon,' founded on the Greek-German lexicon of Passow, he wrote a 'History of Rome' (1855), afterward abridged as 'The Student's Rome.' Consult Thompson, 'A Memoir of H. G. Liddell' (1899).

Liddon, lid'ón, Henry Parry, English clergyman: b. North Stoneham, Hampshire, 20 Aug. 1829; d. Weston-super-Mare 9 Sept. 1890. He was educated at Christ Church, Oxford, where he was graduated in 1850. The year after his ordination to the priesthood he was appointed vice-principal of Cuddesdon College, which bishop Wilberforce of Oxford had recently founded, but resigned in 1859 and became vice-principal of St. Edmunds Hall, Oxford. In 1870 he was chosen as Ireland professor of exegesis, but after the Universities Commission had completed their work, which he looked upon as desecrating, he resigned (1882). From 1870 till his death he was canon of St. Paul's and his sermons under the dome attracted crowds of breathless hearers. He was in fact the last prominent survivor of the theological school represented by Pusey and Keble, and carried its tradition even into the period of the new Oxford movement represented by 'Lux Mundi,' a work which he ardently controvorted. He also was prominent in the controversies concerning the Public Worship Regulation Act, which he opposed, and the Athanasian Creed, which he defended. An inflexible High Churchman, an uncompromising theologian of the Nicene school, he had much influence even where his rigid dogmatism carried no conviction, through the loftiness of his personal character, his transparent sincerity and a noble eloquence, whose power and sweetness recalled the best utterances of Bossuet and Massillon, preachers on whom he palpably bestowed much earnest study. During the last years of his life he was engaged in writing Pusey's life on a voluminous scale, but had completed but three volumes when he died. He was elected bishop of Edinburgh, in 1886, while traveling in the East for his health, but his decline prevented him from accepting. He published many sermons, but the only series likely to prove of permanent importance is his 'Bampton Lectures' 'On the Divinity of Our Lord and Savior Jesus Christ' (1866).

Lie, lē, Jonas Lauritz Edemil, Norwegian novelist: b. Eker, Norway, 6 Nov. 1833. He was educated at the University of Christiania and in 1859 settled as a lawyer at Kongsvinger, to the northeast of Christiania. He went to Christiania in 1868 to support himself by journalism and literary work, and in 1870 became famous with his novel 'The Visionary.' The profits from its publication enabled him to spend some time in northern Norway, and to visit Holland, Belgium, France, and Italy. Returning in 1874, he received the poet's pension from the Storting, resided in Dresden 1877-81 and from 1882 till 1891 lived in Paris in comparative retirement writing his most notable works, and in the latter year he went to Rome, from which he returned in 1892 to Norway. The following are his chief novels and stories: 'The Visionary' (1870); 'Stories and Sketches of Norway' (1872), containing the story entitled 'The Horse

of Nordfjord'; 'The Three-Master Future, or Life in the North' (1873), a series of loosely connected stories or sketches dealing with the life of Norwegian seamen; 'The Pilot and his Wife' (1874), showing a considerable advance on his earlier works; 'Thomas Ross' (1878); 'Adam Schrader' (1879); 'Rutland' (1880); 'Forward! Scenes of the Sea' (1882); 'Life's Slaves' (1883), a powerfully realistic study of a soul involved in the net of circumstance; 'The Family of Gilje' (1884), a lighter story of Norwegian life; 'The Gulf' (1885), treating of the gradual decline of an old Norwegian family; 'Eight Stories' (1885); 'The Commandant's Daughters' (1886), by many regarded as his masterpiece; 'Two Lives' (1887), a penetrating study in the psychology of marriage; 'Maisa Jons' (1888); 'Mischievous Powers' (1889); 'Trold' (1891-2); 'Niobe' (1893), in which his subject is family troubles arising out of differing social, political, or religious views held by parents and children; and 'Grandfather' (1895). He published a volume of poems in 1867, and he has written several dramas, 'Faustina Strozzi' (1875), 'Grabow's Cat' (1880), and 'Merry Wives' (1894). In 1894 he published an important critical work, 'Honoré de Balzac, The Man and the Artist.' Lie's chief works have been translated into German, English, and other languages. He is a realist with a fine sense of humor and profound sympathy with the humble and the unfortunate, and is a master in psychological analysis.

Lieber, lē'bér, Franz, American publicist: b. Berlin, Germany, 18 March 1800; d. New York 2 Oct. 1872. He volunteered as a soldier at 15, and was in the battles of Ligny, Waterloo, and Namur. He served also in the Greek war of independence, recording his experiences in 'Journal in Grecce' (1823). He settled in the United States in 1827, and during the next five years was occupied with the compilation of an 'Encyclopædia Americana' (13 vols.). While professor of history and political economy in South Carolina College (1835-56), he wrote the three great works by which he is best known, 'Manual of Political Ethics' (1838); 'Legal and Political Hermeneutics or the Principles of Interpretation and Construction in Law and Politics' (1839); 'Civil Liberty and Self Government' (1853). In 1857 he became professor of history in Columbia and later of political science in the Columbia Law School. During the Civil War period he was a firm supporter of the Federal government and was frequently consulted by the secretary of war. His war code, officially designated as 'Instructions for the Government of the Armies of the United States in the Field' (1863), made him still more widely known. He was a member of the French Institute and of many learned societies at home and abroad. Consult 'Lives' by Perry (1882); Harley (1899).

Lieber, Oscar Montgomery, American mineralogist and chemist: b. Boston, Mass., 8 Sept. 1830; d. Richmond, Va., 27 June 1862. He was a son of Franz Lieber (q.v.) and was educated at the Universities of Berlin and Göttingen and the School of Mines at Freiberg, Saxony. In 1850 he became State geologist of Mississippi and afterward engaged in the survey of Alabama and South Carolina. In 1860 he went to Labrador as geologist of the Ameri-

LIEBIG—LIÈGE

can astronomical expedition. During the early part of the Civil War he served in the Confederate army and was fatally wounded at the battle of Williamsburg. He published 'The Assayer's Guide' (1852); 'The Analytical Chemist's Assistant' (1852); 'Geology of Mississippi' (1854).

Liebig, Justus, yoos'toos lē'bīg, BARON von, German chemist: b. Darmstadt 12 May 1803; d. Munich 18 April 1873. He studied in Bonn and Erlangen, was graduated in 1822, and the same year went to Paris, where he gained the favor of Humboldt by his paper on fulminic acid and the fulminates, read before the French Academy (1824). He thus obtained access to the private laboratory of Gay-Lussac. In 1824 he was appointed extraordinary professor and in 1826 ordinary professor of chemistry at Giessen. Here he opened the first experimental laboratory for college students, and the university soon became the European centre of chemical studies. He had remarkable success as a teacher, and pupils streamed into his class room from every country. The most illustrious chemists of the last century acknowledge their obligations to him as their master. He gave chemistry a settled position in Germany, and turned it into a real science to be taught and learnt by means of experiment. As an original investigator in the domain of chemistry he has shown himself a reformer of the sciences of physiology and agriculture. He may be said to be the founder of modern organic chemistry, and its necessary method of analysis. He analyzed many organic acids; discovered chloroform and chloral; he made the theory of the composition of ether, and the oxidization of alcohol subjects of new experiments, in the course of which he discovered aldehyde. He determined the basicity of many acids; analyzed the chemical composition of urine and the products of uric acid, and made profound inquiries into the juice of flesh, and its component substances. He raised chemistry from a position of obscurity and unprofitable hypothesis into its present all dominating position by his theory of the constitution of alcohol, ether, etc., and his work on the benzoyl compounds is especially remarkable in this connection. The industrial importance of his discoveries is great. Cyanide of potassium is largely employed in electro-plating and in the manufacture of ferrocyanides. His improved method of producing this cyanide has cheapened manufacture, just as his discovery of aldehyde has led to improved methods in the making of vinegar and looking-glasses. The result of his vast discoveries has been especially felt in the domains of medicine, agriculture, and food-hygiene. His great generalization that the mineral and organic world were composed of the same chemical elements, and were subject to the same chemical mutations, revolutionized science. He traced for the first time the transformation of inorganic into organic substances in plants, from which they were transferred to the organisms of animals. His exact statement of the elements received by plants from the soil and air enabled him to prescribe the composition of efficient fertilizers and thus, in the treatment and analysis of soils, to raise the fundamental operations of agriculture to the level of exact science. See CHEMISTRY; AGRICULTURE.

Consult: Liebig, 'The Natural Law of Husbandry' (1863); 'Animal Chemistry in its Application to Physiology and Pathology' (1846); 'Handbook of Organic Analysis' (1853); Hoffmann, 'The Life-Work of Liebig in Experimental and Philosophical Chemistry' (1876).

Liebknecht, Wilhelm, vil'hēlm lēp'knēht, German Socialist: b. Giessen 29 March 1826; d. Berlin 6 Aug. 1890. He studied at the University of Giessen and later at Marburg and Berlin. He was early interested in the writings of St. Simon, and in 1848 went to Paris to take part in the revolution there; then joined in the unsuccessful attempt to make Germany a republic, and was imprisoned nine months without trial. When released he went to Switzerland, where he tried to unite the trade unions on a socialistic basis, was again arrested, handed over to the French authorities, and banished to England. While there he became an intimate friend of Marx and Engels (qq.v.) and was a member of the Communist League. In 1862 he returned to Germany, continued his socialistic agitation, and in 1865 was banished from Prussia. He went to Leipsic, where he met Bebel (q.v.), was active in trade union organization, and was one of the founders of the Saxony Volkspartei soon absorbed by the German Social Democratic party (1868), of which he was from the first a leading member. In 1867 he was candidate for the North German Parliament, but was under arrest and lost the election; he was later elected. In 1868 he was made editor of the 'Demokratisches Wochenblatt,' the next year enlarged and published under the name of 'Volkstatt.' In 1870 he denounced the Franco-Prussian war, for which he was imprisoned three months, and later so bitterly attacked Bismarck that he was again imprisoned. In 1874 he was elected to the Reichstag of which he was a member almost constantly till his death. He was one of the strongest leaders of his party in that body, and very popular and highly respected among German working-men. In 1890 the name of the 'Volkstatt' was changed to 'Vorwärts,' and Liebknecht was retained as editor. He has written 'Die Grund- und Bodenfrage' (1874), a discussion of the land question from the Socialist standpoint; 'Ein Blick in die Neue Welt' (1887), an account of his visit to the United States; 'Robert Blum und seine Zeit' (1890); 'Robert Owen' (1892); and 'Socialism, what it is and what it seeks to accomplish' (translated and published in the United States). Consult: Aveling, 'Wilhelm Liebknecht and the Social Democratic Movement' (1896).

Liechtenstein, lēh'tēn-stin, a small independent principality, practically a portion of the Austro-Hungarian monarchy and united with the Austrian Customs-Union since 1866, between Vorarlberg, Tyrol, and Switzerland; area, 65 square miles, pop. (1901) 9,477. The surface has a fertile soil, yielding abundance of pasture, corn, wine, fruit, and flax. The capital, Vaduz, has about 1,000 inhabitants. The reigning family date from the 12th century, and are descendants of free barons who became princes of Liechtenstein in 1608.

Liège, lē-āzh, Belgium, (1) the easternmost province bordering on Rhenish Prussia and the Netherlands. Area 1,117 miles. The surface

LIEN — LIFE

is diversified with heights varying from 300 to 2,000 feet, and well wooded. It contains rich coal and iron mines. The northern part called Herveland is exceedingly fertile and highly cultivated, affording pasturage for cattle and producing large quantities of butter and Limburg cheese. Pop. (1900) 826,175. (2) An episcopal city and the capital of the province at the confluence of the Ourthe and Meuse, 54 miles southeast of Brussels. The city has been considerably modernized since 1860 by the construction of fine quays and bridges along the course of the Meuse throughout the city. It has numerous striking public buildings including the Gothic cathedral of St. Paul, the Palais de Justice and the celebrated university, occupying extensive grounds, with special institutes for various sciences, a school of mines, a school of arts and manufactures, and an important library. Liège is one of the largest manufacturing towns of Europe, owing principally to its situation in a district abounding with coal, iron, lead, copper, and marble. Cannons and firearms of every description, steam engines, and machinery, hardware of every kind, watches, jewelry, bronze and other ornaments, woolens, cottons, etc., are made. Liège dates from the 6th century. Pop. (1900) 173,706.

Lien, lē'ēn or lēn, a legal claim on or upon property; a legal right in one person to detain the goods of another until some claim of the former against the latter has been satisfied. Blackstone says a lien may be either particular or general; the former is where the claim of retainer is made upon the goods themselves, in respect of which the debt arises, a claim which the law favors. The other, or general lien, is where goods are retained in respect of a general balance of account, which is less favored. Though general liens are not favored by law, yet in some cases they have become allowed and established by usage, as in the case of attorneys upon the title-deeds and documents of their clients; and factors, warehousemen, and others, upon goods confided to them in the ordinary course of business.

Lieuely, Greenland. See GODHAVEN.

Lieutenant, lū- or lēf'tēn'ant, a military term, which, like captain, and many others, has received gradually a much narrower meaning than it had originally. Its true meaning is a deputy, a substitute, from the French *lieu* (place, post) and *tenant* (holding). A *lieutenant-général du royaume* was a person invested with almost all the powers of the sovereign. Lieutenant-general is the title of the commanding general of each division of an army, personating the general-in-chief. Lieutenant-colonel is the officer between the colonel and major. The term lieutenant by itself, in military language, signifies the officer next below a captain, whether in the cavalry or infantry. There are also second lieutenants ranking below lieutenants. A lieutenant in the navy is the officer next in command to the captain of a ship. He takes rank both in the British and United States services with a captain in the army, and after eight years' service he ranks in Britain with a major. In the United States a lieutenant ranking with a major is called lieutenant commander.

Lieutenant-colonel, a military title, the officer next in rank to a colonel, and the senior of a major. He has actual command of a regiment, and is responsible for the discipline and comfort of the troops under his command.

Lieutenant-general, formerly general officer in the United States army, ranking above a major-general and below a general. The office of lieutenant-general was first created by Congress for George Washington in 1798, during the troubles between the United States and France. It then lapsed till renewed by Congress for Gen. Winfield Scott, who was made lieutenant-general by brevet. In 1864 it was again revived for Gen. U. S. Grant, and continued for Generals Sherman and Sheridan. The grade was also conferred on Gen. John M. Schofield, 5 Feb. 1865, who held it till his retirement, 29 Sept. following. An act of Congress of 6 June 1900 provided that "the senior major-general of the line commanding the army shall have the rank, pay and allowances of a lieutenant-general"; and on the reorganization of the army in February 1901 the grade was revived and President McKinley appointed Maj.-Gen. Nelson A. Miles its incumbent. In 1903 the rank was again abolished, an act of Congress providing for a General Staff, the chief of staff to take the place of the lieutenant-general.

Lieutenant-governor, an executive office of several of the States, ranking next to the governor. He performs the duties of a governor in case of the latter's death, absence from the State, or inability to act, and is presiding officer of the State senate.

Liezen-Mayer, lētsēn-mī'ér, Alexander, Hungarian painter: b. Raab, Hungary, 24 Jan. 1839; d. 1898. He studied at Vienna and Munich, attending the art academies in those places, and afterward entered the studio of Piloty (1862) in the latter city. Under this master he painted his 'Queen Maria and Elizabeth of Hungary at the Grave of Louis le Grand' and 'The Coronation of Charles of Durazzo in the cathedral of Stuhlweissenburg.' Three years later he carried off the first prize at the Munich Academy exhibition. In 1867 he painted 'Maria Theresa'; 'The Child of a Poor and Sickly Mother'; and as drop-scene for the Munich theatre, 'Poesy Surrounded by the Muses.' In 1867 he began to paint portraits, and also furnished illustrations for the works of Goethe and Schiller. During a residence in Vienna (1870-2) he executed portraits of the emperor and many of the nobility. On his return to Munich he painted some ideal figures from Shakespeare's 'Cymbeline,' and some scenes from Goethe's 'Faust'; and in 1873 'Elizabeth Signing the Death Warrant of Mary Stuart' (in the Museum at Cologne), and one of his masterpieces, although its principal merit lies in the perfection of the technique. He produced also many cartoons for woodcut reproduction as illustrations of the poets. For three years he was director of the Art School at Stuttgart (1880-3), when he was appointed professor of historical painting in the Munich Academy.

Life. No definition of life has ever proved quite satisfactory. Some include too much, others omit certain phenomena, a third class assume conditions purely hypothetical, while many are unintelligible. Bichat says that life is "the sum total of the forces that resist

LIFE

death"; Treviranus, that it is "the constant uniformity of phenomena with diversity of external influences"; Duges, that it is "the special activity of organized bodies"; and Beclard, that it is "organization in action." De Blainville's definition is: "Life is the twofold internal movement of composition and decomposition, at once general and continuous." But according to Herbert Spencer this conception is in some respects too narrow and in others too wide. Of his own definition, that it is "the co-ordination of actions," he says—"like the others this definition includes too much, for it may be said of the solar system with its regularly recurring movements and its self-balancing perturbations, that it also exhibits co-ordination of actions." His amended conception of life is: "The definite combination of heterogeneous changes, both simultaneous and successive, in correspondence with external co-existences and sequences." G. H. Lewes suggests the definition: "Life is a series of definite and successive changes, both of structure and composition, which take place within an individual without destroying its identity." This is one of the most satisfactory definitions that has as yet been given. The most recent attempts have been in the direction of proving that life is merely a form of energy or motion, and show the influence which the physical sciences have had in recent years over knowledge and speculation, which formerly were mainly based on biology and theology. The simplest answer to the question probably is: Life is metabolism.

Leaving the subject of attempted definition, it will be profitable to observe some of the characteristics of life as compared with its absence; that is, substantially, a comparison of the organic with the inorganic part of the universe. The boundary between living and not-living matter is much less distinct than rough inspection suggests, but some of the most striking characteristics which distinguish living organisms from other objects of our experience which are not-living may be pointed out. The distinctive properties of living matter are, first, the fact that it is organized; second, that it has the power of perpetuating itself within definite limits by chemically taking and adapting (assimilating) suitable material from the surrounding media, and in the process generating heat (energy) in the absence of which it disappears; and, third, that it has the power of self-reproduction. Life cannot exist without that chemical interchange between the organism and its inorganic environment, and between the constituent parts of the organism which is summed up in the word metabolism (q.v.). Objections have been made to some of the definitions quoted above, and to others, that they assumed the existence of organization. But so far no evidence is present of any living thing without organization. The simplest one-celled animals and plants (see AMEBA; PROTISTA) consist of organized protoplasm. This fundamental living substance, called protoplasm (q.v.), is of complicated structure and chemical composition. Its structure differs in different organisms; but it everywhere consists of a combination of viscous "plasma" and water. The plasma contains the chemical substances upon whose changes life depends. Protoplasm is, however, not homogeneous. At least two kinds are found in every mass, the cytoplasm constituting the major part of the

whole; and the nucleus, the nutritive and reproductive centre. The combination of cytoplasm and nucleus forms a cell. Combinations of cells constitute the bodies of all organisms, large or small, past or present. These combinations are accumulations resulting from the property, characteristic, regularly and fundamentally, only of living organisms, of the doubling of molecules, by which growth is effected.

The fundamental vital phenomena may be regarded as (1) nutrition and (2) reproduction. The conditions under which these activities may be manifested are narrow in general, and the more closely limited in respect to a particular organism in proportion as its organization is more or less complicated. These conditions belong to the environment, from which the organism must take the elements necessary to its continued repair of loss—in other words, get food. Essential elements are oxygen, water, and certain salts; in a word, all the constituent elements of protoplasm, at the least, must be obtainable from the air or water, in order that vitality may persist. It is needful, however, that certain harmful things (poisons) should be absent, or the organism will be killed. Death will also follow excess or deprivation of the proper proportions of the food elements; too much or too little water; a raising or lowering of the temperature above certain points; the presence of light, proper electrical conditions, etc. The simplest animals and plants, consisting of little except protoplasm and water, have great power of resistance to untoward conditions, and the range of diversity in circumstances in which they are able to survive is very wide. Protozoans, eggs of lowly animals, spores of fungi, and the like, slowly dried show the possibility of persistence for prolonged periods without water. Small nematode worms are said to have survived desiccation for 14 years; and certain starchy seeds, kept thoroughly dry, may germinate after 10 or 20 years. As to temperature, dry yeast will live after exposure to 70° C., and a portion survives even at 100° C.; Pasteur heated dry fungoid spores without fatal results to 120° C., but the same when moist were killed at the boiling-point. Some bacteria are said to resist boiling, but the reverse is usually true. Kühne killed marine amoeba at 35° C., while fresh-water forms stood 10° more. Even seeds have been known to withstand 100° C., but it is familiar that a longer exposure to much lower temperature is usually fatal. Higher plants have been known to survive burial under a glacier for four years; and fishes, frogs, etc., have often revived after being frozen hard in ice. Dry yeast, according to Cagniard de la Tour (quoted by Huxley), survived -60° C., but when moist was killed at -5° C.; yet Cohn cooled bacteria to -18° C. without death, and seeds have survived such an extreme as -120° C. To illustrate the diverse sensitiveness of animals, Semper notes that a temperature about the freezing-point of fresh water kills Infusoria but not pond-snails, that the minimum of vital activity in the former was seen at 4° C., in the latter at 12° C., yet the optimum for both is the same, namely, about 25° C. These facts illustrate how wide are the conditions to which some organisms have been able to adapt themselves; but they show that limits exist; and only emphasize the fact of common knowledge that life in its higher manifestations is dependent upon

LIFE AND ADVENT UNION — LIFE-PRESERVERS

the maintenance of a few well-defined conditions, and that innumerable accidents may bring it to a permanent end (see DEATH), whereupon the material which it animated instantly becomes inert matter subject only to the laws that govern the inorganic world.

Reproduction is the means of securing that continuity of life which is one of its primal characteristics, and consists in the separation from the original organism of a part, relatively greater or less in proportion as the organization so divided is simple or complicated, which part is equally endowed with the potentialities of living and reproduction, and normally will reproduce its kind in turn.

For an account of the speculations and reasoning as to the origin of life on the earth, see ORIGIN OF LIFE; PROTISTA.

Life and Advent Union. See ADVENTISTS.

Life-boat, a boat for saving persons from shipwreck, and so built that it can live in a stormy sea. It must be constructed with strength sufficient to resist violent shocks from the waves, the rocky beach, or collision with the wreck; be buoyant enough to avoid foundering, and to float though loaded with men and filled with water; have facility in turning; and when capsized be able to right itself. Such boats are now maintained at most of the life-saving stations in America and Europe, ready to put to sea at once if their services are required, and provided with the means of being conveyed to the beach and launched with all possible rapidity. The first patent taken for a life-boat was as early as 1785. In 1789 Henry Greathead of England patented the best form of life-boat, and by the year 1804 his boat had saved nearly 300 lives. Till 1851 Greathead's invention was almost the sole one in use, though numerous others had been either introduced or proposed; but in that year no fewer than 50 models of improved life-boats were sent to the London Exhibition in competition for a prize offered by the Duke of Northumberland for improved construction. James Peake of Woolwich Dock-yard, by combining the excellencies of the competitive boats, and adding others suggested by his own experience, designed a boat which, gradually improved from time to time, became the recognized model, and has been adopted as the standard for boats in all countries. This life-boat possesses in the highest degree all the qualities which it is desirable that a life-boat should possess:—1. Great lateral stability, or resistance to upsetting. 2. Speed against a heavy sea. 3. Facility for launching and taking the shore. 4. Immediate self-discharge of any water breaking into her. 5. The important advantage of self-righting if upset. 6. Strength. 7. Stowage-room for a large number of passengers. The great breadth of beam (8 feet) in proportion to her length (33 feet) is to diminish the liability to capsize in a heavy sea. The relieving-tubes, by which any water that breaks into the boat is immediately self-discharged, are a most beautiful contrivance. Such are the precautions for the safety of the crew that loss of life in the conduct of the boat is of rare occurrence. The life-boat transporting carriage is an important auxiliary to the boat. The life-boat is kept on this carriage in the boat-house ready for immediate transportation to the spot most favorable for launching to the wreck. In this

way a greater extent of coast can secure the benefits of the life-boat than could otherwise be the case. Even when the launch is from the immediate vicinity of the boat-house the use of the carriage saves much time, which in a case of shipwreck may prove of the last importance. Besides, a boat can be readily launched from a carriage through a high surf, when without a carriage she could not be got off the beach. The machine is admirably contrived, and the boat may be launched from it in an upright position with her crew on board. To render it more manageable and of the greatest possible utility, the fore and main bodies can be detached from each other by the withdrawal of a forelock pin.

Life-buoys. See LIFE-PRESERVERS.

Life-estate, in the common law, as applied in England and the United States, a freehold not of inheritance; an estate or interest in real property for a life, and which is either conventional or legal. A conventional life-estate is expressly created by the act of the parties, and is for the life of the owner, or for the life of another, in which case it is called an estate *pour autre vie*. A legal life-estate is either tenancy-in-tail after possibility of issue extinct; or what in the older country is technically designated courtesy of England, that is, the life-interest held by a husband in his wife's fee-simple or fee-tail estates, general or special, after her death; or dower, that is, the right which a wife has for her life in the third part of the lands and tenements held in fee-simple, fee-tail-general, or as heir in special tail by her husband at the time of his decease. The tenant for life may cut wood to repair fences and for household fuel. If there is an open mine on the estate he may work it for his own profit, but he cannot open one. See ESTATE; FEE; FEE SIMPLE; ENFEOFFMENT; FORFEITURE.

Life-everlasting, one of the everlastings (*Anaphalis margaritacea*), called the pearly or large flowered; also silver-leaf, cotton-weed, none-so-pretty, etc. See EVERLASTING.

Life-insurance. See INSURANCE, LIFE.

Life-mortars. See LIFE-ROCKETS.

Life-preservers are inventions for the preservation of life in cases of shipwreck. In the mercantile marine and passenger ships there are now life-belts for every passenger and every member of the crew. Buoys are carried on the bridge and at the stern of most ships in the mercantile marine. The danger to ships' ordinary life-boats is that, from being so long out of the water, unless attended to they get so dry that when floated they fill. Although against regulations, these boats have been known to be filled with cargo. Sometimes the handiest life-buoy is an empty water-cask, well bunged up, and with ropes around it to hold on by. There are various kinds of buoyant pillows, life-jackets of india-rubber cloth, and mattresses. The cork-mattress can float three men in an upright position.

The life-belt commonly used was designed by Admiral Ward of England. It is made of cork covered with canvas, and is both strong and buoyant. It has four separate compartments, so that if one should be punctured and burst, the belt's buoyant power is not entirely destroyed. Each life-belt must have sufficient extra buoyancy to support a man heavily

LIFE-RAFTS — LIVE-SAVING SERVICE

clothed, with his head and shoulders above the water, and to enable him to support another person besides himself. It must be flexible in order to fit tightly into the shape of the wearer. There is a division between the upper and lower parts so that it can be securely fastened round the waist, and not impede breathing or the muscular action of the chest or arms. See LIFE-BOAT; LIFE-RAFTS.

Life-rafts are various floating apparatus for saving life in case of shipwreck. A life-raft invented in England in 1870 is triangular in shape, and constructed of wood, cork, and rope-netting. It has the advantage of being handy and could be easily hauled to and fro between a ship in danger and the shore. Other patent life-rafts are merely square frames buoyed up by a cask at each corner. Empty water-casks well bunged up are very ready and effective instruments of safety in shipwreck, and should have ropes attached to them to hold on by. Frames of bamboo and inflated skins have long been in use as life-preserveds among different nations, and contrivances more or less ingenious to preserve the buoyancy of the body in case of accidental immersion in water, are resorted to in all countries. Whatever is lighter than water, if used on account of its buoyancy as a means of personal safety, may be considered a life-raft. See LIFE-BOAT; LIFE-PRESERVERS.

Life-rockets are projectiles to communicate between a distressed ship and the shore. These are especially useful where no life-boat can be had, or where it cannot be used on account of the roughness of the sea. They are available, however, only at moderate distances from the shore. By means of them a rope is thrown either from the ship to the shore, or from the shore to the ship, generally the latter, and when communication is thus established a slinging apparatus may bring the crew ashore one by one. Of the numerous projectiles for life-preserving purposes one of the simplest is the heaving-stick, which can be discharged by hand, but cannot be relied on for distances greater than 50 yards. A piece of stout cane two feet long, one end loaded with two pounds of lead, and the other attached to a thin line, is whirled vertically twice or thrice, and then discharged. Kites have been tried, but cannot be relied on with certainty, the most reliable missiles being those that are discharged from a mortar or gun by gunpowder, having a line attached to them. The first trial of this kind was made in 1791 by Sergeant Bell, of the English artillery, who fired his projectile from the ship to the shore, but it was soon perceived that it was better to fire from the shore to the ship. The life-mortar of Captain Manby was invented in 1807, and is practically still that in use, though variations in details have been made on it from time to time. His missile was a shot with curved barbs, resembling the flukes of an anchor, to grapple the rigging or the bulwarks of a ship. The shot was fastened to the rope by strips of rawhide. There was a contrivance for rendering the rope visible to the crew, and another to assist those on shore to descry the exact position of the ship in distress. The life-arrow, a cue-shaped stick of mahogany, with the thinner end projecting beyond the end of the barrel, is fired from an ordinary musket, and can carry 80 yards with a mackerel line attached.

The best lines are those made of loosely-spun Italian hemp. There are several ways of arranging the line so that it may run out quickly without kinking or entangling. Dennett's faking-box for this purpose is now generally adopted. The sling life-buoy is employed in conjunction with the rocket-apparatus. It is popularly known as the breeches buoy (q.v.).

In the United States the mortar is in general use at life-saving stations. At each station a cart is kept always ready packed with all the requisites for the rocket apparatus, and can thus be despatched at once on any emergency. Care is taken that the supplies are regularly renewed before the old are exhausted.

Life-saving Guns. See LIFE-ROCKETS.

Life-saving Service, United States, an important and effective branch of the public service, under the direction of the Treasury Department. The present system was inaugurated in 1871, by the present general superintendent, Sumner I. Kimball, then chief of the Revenue Cutter Service. In June 1878, by act of Congress, it was organized into a separate bureau. The service extends to the coasts of the Atlantic and Pacific, the Gulf of Mexico, and the Great Lakes.

The first life-saving stations in the United States were established by the Massachusetts Humane Society at Lovell's Island and Co-hasset. All efforts for saving life and property in cases of shipwreck were made by this society till 1837, when the President of the United States was authorized to employ ships to cruise along the shores and render assistance to distressed navigators. William A. Newell, afterward governor of New Jersey, witnessed a fearful shipwreck off Barnegat Island in which many bodies were washed ashore, and was so impressed by the sight that when he was elected to Congress in 1848 he introduced a bill for the relief of shipwrecked persons. The result of the passage of this bill was the placing of a few life-saving stations between Sandy Hook and Little Egg Harbor, N. J., and a little later a few stations were established on the coast of Long Island. Volunteer crews were depended upon at all the stations until the introduction of the splendid system which now extends along the entire coast and lake lines of the United States.

In 1903 there were 273 stations, of which 196 were on the Atlantic and Gulf coasts, 60 on the Great Lakes, 16 on the Pacific, and one at the falls of the Ohio, Louisville, Ky. During the fiscal year ending 30 June 1903, there were 697 disasters to vessels, 57 of which were totally lost. Of the 4,337 persons involved, 24 were lost. The value of property involved was \$9,051,150, of which \$1,169,105 was lost.

There are 13 districts in the service, over each of which is a district superintendent. There is also an inspector of life-saving stations at large, and in each district an assistant inspector, all being officers detailed from the Revenue Cutter Service. The business of the assistant inspectors is to look after the buildings, apparatus, drilling of the crews, etc., of their respective districts. Each station has a keeper who has six or seven surfmen under him. The keepers are all made inspectors of customs and so have legal custody of all property washed or brought on shore. The sta-

LIFFEY — LIGHT

tions, generally two-story buildings of six or seven rooms, are built at irregular intervals along the shore from 3 to 20 miles apart, according to the frequency with which vessels approach the land in their course. They are connected by telephones wherever practicable, and the distances between them are patrolled day and night. Each patrol carries a red Coston signal light, which he burns when a vessel is discovered in distress. On the Great Lakes the life-saving stations are kept open from the beginning of navigation in April to its close in December. On the Atlantic coast they are open from 1 August to 1 June, while on the Pacific coast they are open the year round. Each station is equipped with the life-boat (q.v.), guns, mortars, breeches buoys, and other devices for saving life and property.

HORACE L. PIPER,

Assistant General Superintendent, Life-Saving Service.

Liffey, lif'i, Ireland, a river which rises in county Wicklow, flows west into Kildare, then turns northeast and passes through the county and city of Dublin into the Irish Sea after a course of 50 miles.

Lig'ament, in anatomy, human and comparative, a band of white fibrous tissue which connects bones. To this class of tissue also belong the tendons or sinews of muscles, by which these structures are attached to the surfaces of bones. Ligaments differ from tendons in being of a stouter structure, and less liable to give way or to be ruptured. When ligaments break during life they seldom snap across or transversely, but generally tear in an irregular manner. Tendons, on the contrary, when subjected to great strains, break across. Ligaments possess little or no elasticity, and when stretched do not recover their resiliency. To the same class of structures as ligaments and tendons, the fasciae or sheet-like bands of white fibrous tissue spread over muscles and regions also belong. Microscopically examined, both ligament and allied structures exhibit sets of fibres arranged in parallel bundles, imbedded among which little nucleated bodies known as connective-tissue corpuscles are seen. These latter are minute corpuscles of various shapes, and their function has been assumed to be that of ministering to the growth and nutrition of the fibres amidst which they are placed.

Ligao, lē-gā'ō, Philippines, a pueblo of the province of Albay, Luzon, situated near the Inaya River, 22 miles northwest of Albay, the provincial capital, on the main road. It is in one of the best hemp growing regions in the archipelago. Pop. 17,900.

Lig'ature, in surgery, a cord, thread, bandage, etc., by means of which structures are tied or bound. A ligature is used for tying a bleeding artery or other vessel; for tying the pedicle of a tumor to prevent effusion of blood or other fluid after its removal; it may be tightly fastened round the base of a tumor to cause its subsequent removal by arrest of its blood-supply and consequent death. Thread of silk or hemp was formerly employed. Ligatures of animal material are now mostly used, catgut, silkworm gut, etc., also those of silver wire, and they are usually rendered antiseptic by steeping in carbolic acid or other antiseptic solution.

Ligature. See MONOGRAM.

Light. The word light is used in two distinct senses, namely, to designate the sensation which is characteristic of the organ of vision (q.v.), and also as a name for the usual cause of that sensation. This double meaning of the word would result in little inconvenience if there were always a definite relation between the sensation and its cause; but this is far from being true. For example, when we speak of white light, we may mean a sensation which is perfectly definite and familiar to all persons of normal vision, or we may mean that form of energy which can give rise to such a sensation. In this second sense the term is wholly indefinite, since there is an infinite variety of forms of energy which may give rise to the sensation of whiteness. The difficulty, which is a serious one in scientific language, may be avoided by restricting the use of the word to one of its significations, preferably to that of sensation, after the analogy of the use of the word sound. But such a restriction would not be in accordance with well-established usage, and it would necessitate the frequent employment of awkward circumlocutions. Another means of avoiding confusion is to so divide the subjects treated that the sense in which the word is used is unmistakable. This second method has the advantage of conciseness as well as that of being in accordance with the usage of most writers. The present article treats of light as a phenomenon of wave motion, wholly independent of the sense organ which betrays its existence to us. In it the eye is regarded as a simple optical instrument, quite like the photographic camera. This limitation admits of a satisfactory definition of the terms "white light," "yellow light," etc. Thus, by the former term we mean such waves as are emitted by a solid body at a very high temperature, as, for example, the incandescent lime in the lime-light. Any other kinds of waves, even if indistinguishable from these by the unassisted eye, are not white light. Again, yellow light, green light, etc., are the simplest waves which excite in a normal retina the sensations yellow, green, etc.

Theories Concerning the Nature of Light — It is now a little more than two centuries since the Dutch philosopher Huyghens published a paper in which he explained the familiar phenomena of light by waves in a medium that pervades all space and is called the luminiferous ether. His reasoning was so convincing, the explanations so simple, and the experiments supporting his views so apt, that except for the labors of the single philosopher then living who was greater than Huyghens himself, they could hardly have failed to receive at an early day the universal acceptance which they now command. Nine years earlier, in 1669, Newton had commenced his labors in the field of optics, by which, largely on account of fame and authority won in the domain of mechanics and astronomy, he established a theory of light which remained almost unquestioned for nearly a century and a half. Newton supposed light to consist in extremely small particles of matter projected from shining bodies with enormous velocities. We now know that this hypothesis was not only less fruitful than that of Huyghens, but, even with the comparatively limited range of optical

LIGHT

phenomena known to Newton and his contemporaries, was also less probable.

According to this view of Newton, visual sensations are produced by the impact upon the retina of minute corpuscles emitted from luminous bodies which pass freely through transparent substances, differences of color being due to differing size in these small bodies. When these corpuscles approach the boundary of an optically denser medium, they are subjected to a force of attraction which causes them to deviate from their otherwise rectilinear paths. This is the explanation of the phenomenon of refraction. The secondary phenomenon of dispersion was very simple and naturally explained by an assumption that this attracting force varies with differing size. Singularly enough, the explanation of one of the most common phenomena, that of partial reflection at the boundary of a transparent medium, offered formidable difficulties: How is an attraction which is necessary to account for refraction also to act as an apparent repulsion for those corpuscles which are thrown back from the surface in reflection? This is a difficulty which the advocates of the Newtonian theory have never been able to meet in a satisfactory manner.

When Newton attempted to extend his theory to the explanation of the colors of thin plates, a subject which he was the first to investigate in a scientific manner, it was found even less satisfactory. He was obliged to supplement it with the highly artificial hypothesis that the corpuscles experience periodic changes in the ease with which they enter a refracting body. Even this addition to the theory fails to yield more than a rough approximation to an explanation of the phenomena, since the blackness of the central spot in Newton's rings apparatus, when the plates are brought into contact, is in contradiction with it. But it was only on account of a subsequently accumulated knowledge of optical phenomena which refused to adjust themselves to this theory, no matter how it might be modified, that its final overthrow came about. This not only required a long time, but also a champion of transcendent power to break with a system which had the force of tradition as well as the authority of the greatest of all philosophers to support it.

From 1704, the date of the publication of Newton's Optics, until 1815, the corpuscular theory was hardly questioned; at any rate, it reigned supreme in all treatises on light, and it was questioned only by a very few investigators who failed to acquire an influence that was anywhere decisive. In the latter year Augustin Fresnel, a young French government engineer, entered upon a career of scientific activity which proved of almost unprecedented brilliancy and success. Thus, as far as it bears upon the purely physical theory of light, may be regarded as completed in 1826. Beginning with a highly philosophical criticism of some of the accepted doctrines of optics, supported by the most apt appeals to ingenious experiments, he quickly extended his investigations until he embraced nearly all phenomena of light known to his contemporaries; and this with such success that he not only established as beyond question the essential truth of a wave theory but brought it to so high a degree of completion that his views were long supposed to be practically final. On

account of the importance of this work of Fresnel in the history of physical science of the past century, it is well worth while to briefly review its character.

The phenomena of diffraction first engaged the attention of Fresnel. It had long been known that the shadow of an opaque body cast by a point-source of light is somewhat different from what would be supposed from simple geometrical considerations, the difference consisting chiefly in an encroachment of the light upon the borders of the shadow. Newton, who called this phenomenon inflection, attributed it to an attractive force exerted by the opaque body upon the corpuscles while in its neighborhood, thus causing an inbending of their paths. Fresnel showed that this explanation was quite untenable, since the inflection caused by the back of a razor is exactly the same as that caused by the edge, although in the former case it is manifest that the time during which the corpuscles are subject to the deflecting force is far greater than in the latter. By similar appeals to ingenious crucial experiments he demonstrated that none of the current theories was sound; but far from resting here, he showed that all the observed phenomena could be perfectly accounted for in the undulatory theory of light, by an application of the principle of Huyghens. Extending this principle, so fertile in his hands, to wider fields in the domain of optics, he found in every case that the new method was adequate to yielding perfectly satisfactory results. With quite simple and natural hypotheses as to the conditions which must exist at the common boundary of two transparent media, he was even able to deduce quantitative laws governing the phenomena of reflection and refraction, which accord surprisingly well with experiments devised to test them.

A few years before the commencement of Fresnel's activities, Malus, while looking through a double-image prism, observed that the two images of a distant window which happened to be in such a position as to reflect light strongly to his eye, were quite different in brightness, and that under some conditions one image might entirely disappear. Further study showed that all ordinary transparent substances were capable of thus modifying light by reflection, and that the modification is complete at an angle which is simply related to the refractive index; moreover, that under the latter conditions the light would be transmitted through doubly refracting crystals in certain directions without bifurcation. Such modified light is called polarized light, and the phenomena thus briefly described are two of the simplest of an enormously extensive class, many of which are of extraordinary beauty. This discovery and those which quickly followed in the same field presented a host of new and difficult problems to physicists. Of the many active and able workers in this domain Fresnel was easily the leader. In a very few years he had proposed and developed a general theory of light which embraced these new phenomena and which stood almost unquestioned until our own day; and even now the most essential principles of his theory are wholly unshaken. In its barest outlines the theory may be described as follows: Fresnel assumes that the motion of the particles which constitutes the vibrations of light is always in a direction at

LIGHT

right angles to the line of propagation of the waves. When the paths of the particles are quite irregular or without order, the light is ordinary light; but when the paths are similar, whether straight lines, ellipses with their axes parallel, or circles with a common direction of motion, the light is said to be polarized. From this simple hypothesis he succeeded in erecting an extraordinary structure which harmonized and explained nearly every known phenomenon of light in a manner that until the most recent times practically withstood all destructive criticism. Even recent achievements in this field of science have been supplementary to, rather than subversive of, Fresnel's general work. Of the phenomena known to his contemporaries, that of dispersion alone was unconsidered by him, a phenomenon which obviously depends upon the ultimate molecular structure of the refracting substance and which has recently been reduced to comparatively simple laws. This great work of Fresnel was looked upon, as indeed it well deserves to be, as one of the greatest monuments to the human understanding—comparable to Newton's doctrine of universal gravitation—and it long remained of almost unquestioned authority. Ultimately, however, one of its fundamental postulates, namely, that the vibrations are always at right angles to the direction of the motion of the light, began to give rise to difficulties. The fact also that the theory could not determine specifically whether the direction of vibration of plane polarized light is in the plane of polarization or perpendicular to it was not only a manifest incompleteness, but it was a constant stimulus to a critical inspection of its premises. The more these points were studied the more insoluble the difficulties appeared, until there came to be a tolerably widespread belief that the theory was not only incomplete, but that in some way it must be essentially in error. To acquire a notion of what modern science has done to clear up these points, we must first review a class of phenomena which seem to be totally unconnected with optics, but which in the end will afford a very remarkable example of the tendency of all science toward unity.

In 1845 Faraday discovered that if polarized light is passed through a transparent substance in a magnetic field and in the direction of the field, the plane of polarization is rotated. The amount of rotation for a given substance is found to be proportional to the strength of the magnetic field and to the length of the path in the material. As many substances, such as turpentine, a solution of common sugar, quartz crystals in the direction of their crystalline axes, etc., present us with a similar fact, this would not be so surprising save for a remarkable difference in the two cases which may be thus described: When the plane of polarization is rotated by passing through a sugar solution or a similar body, and the transmitted light is reflected back upon its course so as to retrace its path, it is found that the original angle of polarization is perfectly restored by a precisely equal rotation in the opposite direction in the return; but a similar experiment upon the body giving the magnetic rotation shows a doubled change of angle. This indicates that, although in the first case we must explain the rotation by the molecular constitution of the material, we are not permitted to suppose that the mag-

nctic field has produced a similar molecular structure in the second case, since the rotation is constant in direction irrespective of the direction of motion of the light. Of course, from the known nature of magnetism, this is equivalent to asserting that there must be some relation between light and electricity. But this is not the most obvious connection between these two classes of phenomena, for as we now know, the earliest division of materials in accordance with their electrical properties involved a classification according to their most characteristic optical properties also. Thus all conductors of electricity, excepting only those liquids which undergo a chemical decomposition when they transmit an electrical current, and therefore belong to an obviously different class, are extremely opaque to light; conversely, all substances which are good insulators are also transparent to light, at least to an extent which would make a sheet a few hundred-thousandths of an inch in thickness appear perfectly transparent, although such a sheet of metal or similar conductor would not differ greatly in opacity from a thick plate. An excellent illustration of the generality of this law is furnished by the element carbon, which in the dense opaque form—like graphite, for example—is a very good conductor of electricity, but in the form of the transparent diamond is an insulator.

Before the middle of the 19th century two methods of measuring electrical magnitudes had been developed; one of these is based upon the repulsion which exists between two electrically charged bodies, and the other upon the repulsion which exists between two similar magnet poles. Elaborate and repeated investigations have demonstrated that if a given electrical magnitude is measured according to one of these systems, and the value thus found is compared to a measurement of the same quantity in the other system, the ratio involves a velocity only. This statement is quite independent of the kind of magnitude chosen for the experiment. Within the limit imposed by unavoidable errors of observation the value of this velocity always appears to be the same as the velocity of light.

Here, therefore, are three distinct relations between light and electricity, which have long been known and to no one of which it is possible to attach any *a priori* reason. It was left to Maxwell to illuminate this obscure field. His long and successful investigations in electricity and magnetism, especially his efforts to reduce Faraday's brilliant discoveries to correlation and to a consistent scientific statement, led him to the conclusion that light itself consists of electrical vibrations. He attempted to test the validity of this hypothesis by every means at his command. For example, according to his theory a non-magnetic substance ought to have a dielectric constant, or what Faraday named its specific inductive capacity, equal to the square of its index of refraction. This indicated relation was found to hold with all expected precision in some cases, but to be widely removed from the truth in others. Again, since, according to the theory, only those substances are transparent which will offer a resistance to the motion of electricity within them analogous to elastic reaction, there ought to be a determinable relation between electrical conductivity and opacity. Maxwell attempted to find this rela-

LIGHT

tion in the case of gold-leaf, which is sufficiently thin to transmit a measurable portion of the light falling upon it. Notwithstanding that the discrepancy was here found disappointingly great, the gradual accumulation of knowledge of the more recondite phenomena of the electrical field had led the great majority of physicists to the conclusion that Maxwell's theory was at least a close approximation to the truth, and accordingly one of the most brilliant discoveries of the 19th century. This may be regarded as a fair statement of the attitude of the world of science in 1888, when Hertz, a German physicist, made a series of remarkable experiments which have eliminated all possible doubt as to the essential verity of Maxwell's theory of light. Fortunately it is not difficult for us to gain a sufficient knowledge of the character of these experiments to make clear their general bearing.

It had long been known that a Leyden jar suddenly discharged through a thick wire gives rise to an oscillatory current of very brief duration, and that in certain simple cases the period of the oscillations can be calculated with considerable accuracy. Hertz recognized that during the time of discharge such an electrical circuit must be a source of oscillatory changes in the magnetic field, which, if the views of Maxwell are in accordance with fact, should be propagated through space with the velocity of light. Although it is difficult, if not quite impossible, to measure directly this velocity, if one knows the wave-length and the period it is perfectly easy to deduce the velocity from these two elements, since in its period every wave moves a distance equal to its own length. In these experiments the period was calculated from the elements of the electric circuit; it only remained therefore to determine the length of the waves. Hertz accomplished this in the following simple and ingenious manner: At a considerable distance from the source of the waves he placed a large sheet of metal perpendicular to its direction from the source. From this sheet the waves were returned upon themselves by reflection. Now, a well-known fact in wave motions is that when two systems of waves of like period are moving in opposite directions, they combine to form a system of standing waves of half the length of the free waves. The regions where motion is destroyed by this kind of interference are called nodes. Hertz demonstrated the existence and position of these nodes by means of an apparatus which possessed the same electrical period as the source. This apparatus he called a resonator. The value of the velocity of these waves deduced from his observations differs no more from the known velocity of light than would be expected from the unavoidable errors of observation; thus it complies with the requirements of Maxwell's theory. These waves, therefore, are shown to differ from light waves only in their enormously greater wavelengths, and that they must be subject to all the established laws of optics which are independent of the length of the waves. The last conclusion was thoroughly tested by Hertz by a series of most interesting and convincing experiments. He found that strictly according to the laws of optics these waves are reflected from the surfaces of all bodies which conduct electricity; that they readily pass through substances which

behave as insulators; and that in passing from one insulating medium to another the direction of propagation is altered in accordance with the law of sines. Further than this, he showed that such electrical waves admit of polarization, and they are therefore characterized by motions at right angles to the direction of propagation. During the time which has elapsed since these investigations a host of experimenters have improved the methods and apparatus of Hertz, and have largely extended the range of wavelengths that can be observed. On the other hand, many investigators have been employed in the application of analysis to both the old and the new problems in optics. The difficulties which attach to Fresnel's mode of regarding the optical phenomena of crystalline media are found to disappear, and all the complex phenomena of light admit of explanation from a consistent body of premises.

Reflection—Refraction—Dispersion.—When light waves originating at a point fall upon a surface separating two media, the system of waves is broken up into two systems, one of which remains in the first medium, though moving in a changed direction, and the other entering the second medium. The former system constitutes reflected light, and the latter, also in general changed in direction, is called refracted light. If the bounding surface is smooth the phenomena of reflection and of refraction are regular and the modified paths of the light can be calculated. The total intensity of the reflected light varies greatly with the nature of the media on either side the interface and also upon the angle at which the wave surfaces meet this surface. If we consider only the case of the first medium being air, we may describe two general cases of interest. (1) If the second medium is a transparent substance, like most liquids, ice, glass, etc., the reflected light is ordinarily of small intensity as compared to the incident light, but increases with increasing angle of incidence, until, as this angle approaches 90° , the rate of increase becomes very great. (2) If the second medium is a metal the reflected light is ordinarily a large portion of the whole, but its intensity does not vary greatly with the angle of incidence. Turning now to a consideration of the light which passes the interface and enters the second medium we find that in some substances these waves will go a great distance without notable diminution of intensity. Such substances are called transparent. In others, described as opaque, the light waves are converted into other forms of energy in longer or shorter distances, and are destroyed as light. In the case of metals and other good conductors of electricity this destruction follows a penetration of only a few millionths of an inch. The laws which determine the directions of the reflected and refracted light are simple. Calling the angles which the incident waves, the reflected waves, and the refracted waves, make with the surface separating the two media, the angles of incidence, of reflection, and of refraction, respectively, we have for the law of reflection the angle of reflection is equal to the angle of incidence, and for refraction, the sine of the angle of incidence divided by the sine of the angle of refraction is equal to the velocity of propagation of the waves in the first medium divided by the velocity in the second medium. These laws are

LIGHT

not absolutely without geometrical ambiguity, but are made so by the addition that the change of direction in both cases is the least possible. If the refracted light is observed critically it will be found that the direction varies somewhat for lights of different colors, so that, if white light is incident, the light will be arranged in direction according to its component colors, the red being least changed, then yellow, green, blue, and, most of all, violet. This phenomenon is called dispersion. Since the maximum difference of deviation for small angles of incidence is never more than a small part of the whole—very few substances exhibiting a ratio greater than one twentieth—dispersion should be regarded as a secondary phenomenon of refraction.

Optical Images—Optical Instruments.—When light waves originating at a point are modified by one or more smooth surfaces—either by reflection, or refraction, or by a combination of the two—so that after these modifications they either pass through a new point or seem to do so, this new point is called the optical image of the first. To distinguish the cases of real points from those which only appear to be new centres the terms real image and virtual image are employed.

If an optical system can form an image, real or virtual, of a point, it follows from the law of continuity that it will also form simultaneous images of near lying points with a like degree of precision; the images of remoter points, however, may be, and in general will be, imperfect. The simplest of all optical systems is a plane mirror, and it is the only optical instrument which is absolutely perfect, provided only that it is not of too small dimensions. Such an instrument forms virtual images of all points in front of it, the sources and images being symmetrically placed with reference to the plane of the mirror. Bodies of transparent substances bounded by smooth curved surfaces, ordinarily spherical surfaces, are called lenses. Almost all optical instruments employ lenses for producing the required modification on transmitted light. If a lens increases the curvature of the wave-surfaces which pass through it—which in general requires the middle of the lens to be thicker than its periphery—it will produce real images of remote objects near its geometrical axis. Such a lens is called a *positive-lens*. A screen to receive the images and an opaque enclosure to shield it from extraneous light constitutes the important instrument known as the camera obscura. One of the earliest optical instruments invented, it has only been of importance since the discovery of a method of fixing the images a short time before the middle of the last century. The requirements of modern photography, especially the demand for brightness and wide angular extent in the images, have led to inventions of wonderfully complex camera lenses, so that ordinarily they are made of combinations of from four to ten different lenses, involving two or three different kinds of glass in their construction.

The eye is properly a camera obscura, in which images of objects neither too near the observer nor too far from the axis of vision are formed upon the retina as a screen. The most important difference between the eye and the photographic camera lies in the fact that the

interior of the eye is filled with a substance optically different from air, which introduces some remarkable modifications in the phenomena of vision. These may be ignored in this casual review of the construction and function of optical instruments.

In almost all optical systems, excepting the camera obscura, the eye is a necessary part in use, and it is therefore convenient to specify the conditions under which distinct vision is possible. To a normal eye, any object very near the axis of vision can be distinctly seen if it lies at a distance comprised between five or six inches for a nearer limit and infinity for the farther. Thus, the moon and a printed page held at the customary distance for reading can be seen equally distinctly. We shall assume a distance of 10 inches as a standard of comparison.

Microscope—Telescope.—If a small object be brought quite close to the eye it will appear larger, but when too close vision will be indistinct. This is because the refractive power of the eye is insufficient to cause the light waves to form new centres at the retina; but if the refractive power of the eye be suitably increased by the aid of a positive lens placed between it and the object, vision is rendered distinct with the increased apparent size. A lens so used is called a simple microscope and the ratio of the apparent diameter of the object to that which it would have at the conventional distance of 10 inches is called the magnifying power of the microscope. Since nature presents us with innumerable examples of such microscopes in small drops of water, of transparent resins, etc., the phenomenon has doubtless been known since prehistoric times, and we have the best of reasons for believing that some of the artisans of antiquity employed magnifiers as aids in their work.

There is no theoretical limit to the magnification attainable with simple microscopes except that set by the nature of light itself, but very high powers demand inconveniently small lenses and such close approximations to the eye that illumination of the object becomes difficult. These difficulties can be greatly reduced by employing two systems of positive lenses, one of which serves to form a *real* and enlarged image of the object, while the other is a simple microscope used to observe the real image quite as if it were the object itself. The former system is called the objective, or object-glass, and the latter the ocular, or eyepiece. The instrument thus constituted is called the compound microscope, and its magnifying power is equal to the product of that of the objective into that of the ocular. The compound microscope was invented about the middle of the 17th century, but it was not perfected so as to be of real value as an instrument for scientific research until after the second decade of the 19th.

If a lens, or lens system, is employed to form a real image of a distant object and this image be viewed through a microscope, the combination forms a telescope. Since the real image is in general inverted, the object appears inverted to the observer if he employs a simple magnifier as an ocular, but it appears erect if the ocular is a compound microscope. The inverting telescope is optically superior and is universally used for astronomical observations,

LIGHT

but for terrestrial observations the second type is ordinarily preferred, which, when it is desired to distinguish it by a name, is called a terrestrial telescope, or a spy-glass. The terms objective and ocular are also applied to the two lens systems in the telescope.

Since concave mirrors can also produce real images of distant objects they may be used in place of the objective. Such instruments are called reflecting telescopes; they have been very extensively used for astronomical purposes in the past.

Achromatism—Achromatic Combinations.—Newton was led by his experiments to conclude that the secondary phenomenon of dispersion bears a constant ratio to the refraction. It follows from this that a separation of composite light into colors is the inevitable concomitant of change of direction by refraction, and that this imposes a somewhat narrow limit upon the power of all optical instruments involving refraction. This belief led him to invent the reflecting telescope, which remained the leading form for astronomical purposes for more than a century. About the middle of the 18th century, however, Dolland found that Newton's conclusion was founded upon too limited a range of experiment and showed that it is possible, by a combination of two or more materials, to secure a change of direction of light by refraction with little or no evident dispersion. Thus, he found that a prism of crown glass, say of 10° , combined with a prism of flint glass of 5° , turned in an opposite direction, would yield a deviation nearly as great as a prism of crown of 5° and without the colors of dispersion. Such a combination is called an achromatic combination, and a pair of lenses similarly combined to give colorless images, is called an achromatic lens. All refined optical instruments utilize this invention of Dolland. In telescopes the objective ordinarily consists of two members only, a positive crown lens combined with a negative (diverging) flint lens; in microscope objectives there are rarely less than four lenses, and sometimes, in the case of very high powers, not less than ten.

Interference Phenomena—Diffraction.—That light is in fact some form of wave-motion does not appear from the phenomena of reflection and refraction in their commoner manifestations, although if the acting surfaces are made very small there are deviations from the simple laws given above which inevitably lead to a wave theory for an adequate explanation. For the present purposes it seems far better to describe some of the simpler and easily produced phenomena which demonstrate the wave-motion.

One of the most striking properties of all varieties of waves is their propagation independently of the state of motion of the medium in which they exist, for example, water waves of all possible lengths and having all possible directions of propagation may coexist on a single surface of water. In familiar acoustic phenomena we have excellent analogies which will greatly help in the comprehending of the less familiar optical phenomena. If two tuning-forks of exactly the same pitch be sounded together it is found that there are regions where all evidence of sound vanishes, provided that the forks are equally loud. These regions of silence are those where the maximum of density due to one set

of waves corresponds with the minimum of the other set, and they are so simply related to the positions of the two forks that having established their places, it is easy to deduce from the geometrical relations the length of the waves. Could we get two sources of light which emitted waves exactly alike, there should be corresponding regions where illumination from the two sources would be wanting, provided that light is in fact produced by a wave-motion. Since, however, the ultimate sources of light are the molecules of luminous bodies and we are unable to control such small bodies, so simple a test is impossible; but a perfect optical image of a source is exactly like the source itself, hence, if light is allowed to fall upon a screen and a portion of the same radiation is reflected by a mirror upon the screen, the conditions for interference are met. The experiment is a delicate one and liable to escape observation, only, however, because of the shortness of the waves. Fresnel tried the experiment, not only by using two mirrors, enclosing an angle a very little less than 180° , but also by using two prisms of very small angle, with complete success. The advantage of using a pair is obvious when similarity of the two sources—here two virtual images of the same source—is considered. His measurements showed that the waves which are found in ordinary white light have all lengths between those of $\frac{1}{1400}$ and $\frac{1}{1500}$ of an inch, the former being that of the extreme red of the prismatic spectrum, and the latter of the extreme violet. The mean value for white light may be taken as $\frac{1}{1450}$ of an inch.

A much easier, though less simple, method of exhibiting interference phenomena is the following: If a hole, less than $\frac{1}{10}$ of an inch in diameter, be pierced in a piece of paper, a distant bright point, such as an arc light or the bright point of a mercury thermometer-bulb in sunshine, will appear to an eye looking through the hole as a disk surrounded by one or more concentric rings. If now a second similar hole be made within less than $\frac{1}{10}$ of an inch from the other and the experiment be repeated, the disk will appear brighter and traversed by a series of dark lines perpendicular to the direction of a line joining the two holes. These dark lines mark the regions of complete interference and are exactly like the dark bands produced by Fresnel's method. The fact that the point-source of light appears as a disk of appreciable magnitude is also explicable by the fact that light is a wave-motion. Broadly stated the condition is this: if light consists of waves, we ought not to expect that the laws of reflection and of refraction will hold unmodified when the acting surfaces are no longer large with respect to the length of a light-wave. These deviations from the laws are called diffraction.

Since most of the light with which we ordinarily experiment is composite, that is, made up of a combination of many different wave-lengths, the places of complete destruction of illumination differ for differing wave-lengths. Such phenomena are therefore generally, sometimes splendidly, colored. Familiar cases of simple interference are presented by thin reflecting plates, such as soap-films, rifts in transparent media, as in precious opal, etc. In these cases we have the two sources produced by reflection from the two sides of the plates, and the phe-

LIGHT

nomena are generally known as the colors of thin plates, first studied by Newton.

Diffraction phenomena are even more commonly seen. The peculiar lustre of satin spar, of the gems known as cat's-eye, and of the star sapphire, find their explanation here. The iridescence of mother-of-pearl and of certain feathers, and the brilliant colored pattern seen when an electric arc light is viewed through a fine and uniform fabric, like silk or the web of many feathers, are diffraction phenomena of greater regularity than the former group.

Optical Phenomena of the Atmosphere.—Of the many optical phenomena which belong either to the air as a transparent body or because of foreign bodies temporarily suspended in it, mirages, coronas, rainbows, and halos are among the most striking. The refractive power of the air increases with its density, and, as this is increased both by pressure and by lowering of temperature, there results varying effects of refraction. With the normal condition of the air, in which the density decreases in a geometrical ratio as we rise above the surface of the earth, the only very obvious effect is to prolong the length of the day to twice the time which it requires the sun to sink at the horizon by its own diameter. Atmospheric dispersion is also present, but is not sufficiently marked to be detected by the unaided eye, although conspicuous enough with a telescope under favorable conditions. The scintillation of the stars, however, is a direct effect of atmospheric dispersion.

In the not infrequent cases when the air departs widely from the normal law of continuous decrease of temperature with increasing height above the surface of the earth, the paths of the light waves which are nearly horizontal may change the direction of curvature between the object and the observer, in other words, may have points of inflection. In low latitudes the prevailing condition, when such abnormal refraction may be observed, corresponds to a lower layer of air at a higher temperature than that immediately above. In such cases distant objects near the horizon appear lifted above their real positions and portions of these much elongated vertically. A further development shows inverted images, generally without much distortion, underneath the raised images. Over sun-heated plains the inverted image is that of a portion of the sky, whence the effect of a sheet of water between the observer and the horizon. In high latitudes it is sometimes possible to find the condition of a layer of much cooler air in contact with sheets of ice or of cold water, in which case the inverted image is seen above the erect image. These phenomena are known under the name of mirage.

When the atmosphere is not quite clear one may sometimes see colored circles concentric with the sun or moon, generally not more than four or five times the diameter of the sun, and invariably having the inner edge blue. Such circles are called coronas. They are diffraction phenomena produced by very small spherical drops of water suspended in the air, and their diameters are in an inverse ratio to the diameter of the drops to which they are due. The only necessary conditions for well developed coronas are smallness and general uniformity of size in the drops.

When sun-light falls on drops of water which are not small compared to the length of a light

wave, an entirely different phenomenon, involving reflection, refraction and dispersion, results. It can be shown that, when flat wave-surfaces of light enter a sphere of water, there are two cases in which a portion of the wave emerges from the drop still nearly flat, and that in these directions, therefore, the light will be transmitted with relatively great intensity. The first case corresponds to refractions at entrance and emergence with a single interior reflection; and the second case to the two refractions separated by two interior reflections. The total change of the direction of the light in the former case is 138° , and in the latter, 231° . It, therefore, follows that all drops at these two angular distances from the sun should appear relatively bright, in other words, that opposite to the sun there should appear two concentric circles under proper conditions of illumination, one, much the brighter of the two, of 42° radius, and the other of -51° radius. The secondary phenomenon of dispersion causes these angles to vary continuously for different wave-lengths, hence the circular arcs, constituting the double rainbow when perfectly developed, appear as bands of prismatic colors. It is not difficult to see that the primary bow, often the only one which can be traced, must be red on the outer border, whence we conclude from the algebraic sign attached to its radius, that the secondary bow should present the red border on the inner margin.

When the temperature is low, water cannot exist in the form of drops, but only in that of snow crystals and of a perfectly transparent vapor. On those occasions when there are numerous ice crystals of very regular form suspended in the air and illuminated by the sun or the moon, we may see one or more of a series of highly complicated phenomena which bear the names of halos, parhelia, sun-dogs, etc. A bare description of all the features which have been observed and recorded would demand far more space than is available; only the most common ones can be noted here. The simplest form of ice crystals, and the only form which is necessary to produce all the known forms of halos, is that of a right hexagonal prism. Such a body supplies two refracting angles, namely, that of 60° contained between two alternate faces of the prism, and that of 90° embraced between each of these faces and a base. As light traversing a 60° prism of ice has a minimum deviation of 22° , if there are present a sufficient number of such prisms between the sun or moon and the observer, the luminous body would seem to be surrounded by a concentric circle of 22° radius, having, on account of the secondary effect of dispersion, a red inner margin and a pale bluish outer one. Similarly the rectangular edges would give rise to a colored circle of 44° radius. The smaller circle can be seen very frequently — perhaps on sixty to eighty days a year in our latitude — while the 44° circle is rarely seen.

When the length and width of a small hexagonal prism differ greatly, it will not remain while falling through quiescent air in a purely chance position, but it will set itself more or less perfectly in a definite position with respect to a vertical. Thus a flat prism will fall with its base horizontal, and an elongated crystal will maintain its axis nearly horizontal. This peculiarity in falling crystals produces a large number of features in complicated halos which are

LIGHT—Lighthouse

generally recognizable because they are all symmetrical with respect to a vertical circle passing through the sun. Some of these are comparable with the most brilliant rainbows in their coloring. The most familiar of this class of phenomena are the two bright prismatic spots to the right and left of the sun respectively, having the same altitude as the sun and their red side turned toward the sun. When the sun is very low they are 22° distant and appear merely as bright portions of the inner halo, but as the altitude of the sun increases they increase their angular distances, and above a moderate altitude they disappear. These spots are called parhelia, or sun-dogs; they are sometimes the only feature of the halo visible and are by no means infrequent. CHARLES S. HASTINGS,
Sheffield Scientific School, Yale University.

Light, Therapeutics of. In medicine light has been used from the earliest times, and the therapeutic application of sunlight is an empirical mode of treatment, in many diseases, which has been handed down through generations. Only in recent years, however, have more definite forms of light-therapeutics been applied, but with the discovery of the X-ray by Röntgen began a new era. The reaction of the human body to different forms of light is very striking, and however various the sources of light, the mode of reaction is often marvelously similar. Thus, the surface capillaries of the skin are dilated, there is exudation of serum into the subcutaneous tissues, and the nerve-endings are stimulated. The results of the application of light widely vary, the variations depending upon the area exposed and the part affected. There is one form of sunburn resulting from direct action of the rays of the sun, and similar burnings have been produced by X-rays and by means of radio-active substances.

At the present time sunlight is used as a general tonic, and as a special tonic to the skin, while as a disinfectant its powers are systematically applied. Modified electric light, X-rays, and radio-active substances are now extensively employed in the treatment of certain forms of new growths of the skin and of the interior body. Lupus is readily cured by means of the Finsen light, and superficial forms of cancer of the skin, and even cancers of internal organs have been cured by means of the X-ray. The X-ray, moreover, produces marked stimulation of the skin, with sweating and at times loss of hair, so that it may be used as a depilatory agent. It is not unlikely that the applications of the X-ray and of radio-active bodies, such as radium, polonium, uranium, etc., will within a few years undergo profound modifications. The study of scientific radiotherapy is only in its infancy. See RADIUM; X-RAY.

Light of Asia, The, a noted epic poem by Sir Edwin Arnold, published in 1878 in eight books. It attracted general attention at its first appearance and familiarized the average reader with the teachings of Buddha. The poem is smoothly written, with not a little beauty of description and movement, but is not the great work its early admirers imagined. The poem has been translated into many languages.

Light That Failed, The, a novelette by Rudyard Kipling (q.v.), published in 1890; the first long story written by this author. The story was dramatized and received its first presentation in 1903, Forbes Robertson appearing in the title-role.

Light-Horse Harry. See LEE, HENRY.

Lighter, a flat boat or barge for transporting merchandise on rivers and canals, and to and from vessels moored in a stream, or where they cannot be laden from or discharged on to a wharf or pier alongside.

Lighthouse, a structure on some conspicuous point of seashore, island or rock, or on the bank of rivers and lakes, from which a light is exhibited at night as a guide to mariners. Lighthouses are generally placed on salient points, each requiring structures specially designed to meet the exigencies of varied sites. When placed on headlands or large islands lighthouses are very much alike in general features, the differences being mainly in the height of the towers, depending on the distance at which the light requires to be seen, and the lighting apparatus. Towers erected on isolated wave-swept rocks in the open sea, such as the Eddystone (now superseded by Sir James Douglass' tower), the Bell Rock, Skerryvore, and Chickens Rock lighthouses, in Great Britain; the Minot's Ledge and Spectacle Reef in the United States, and Bréhat in France, are triumphs of engineering.

History.—The history of lighthouse building and illumination may be said to extend over a period of more than 2,000 years; but the regularly organized life-preserving system of modern lighthouse engineering goes back very little further than the beginning of the 19th century. None of the early lighthouse buildings now exist. The Pharos of Alexandria (331 B.C.) gave its name to its successors. The Romans built lighthouses at Ostia, Ravenna, Puteoli, and other ports. The Phoenician Pharos at Coruña was repaired during the reign of the Emperor Trajan, was re-established as a lighthouse about 1634, and in 1847 had a dioptric apparatus placed in it. On the cliff at Boulogne there are the remains of a lighthouse ascribed to Caligula (40 A.D.), and at Dover there are remains of another Roman Pharos. Until the end of the 18th century the lighthouses of Great Britain and the United States were few in number, and of an inferior description in the great essential of a lighthouse, namely, sending the greatest number of rays of light toward the horizon. Many of the public lights in England were private property, as was also the case with the Isle of May in Scotland, the patent for which was ratified in 1641. There were only 25 lighthouse stations and six floating lights in England at the beginning of the 19th century. The coast and harbor lights in Great Britain and Ireland are now upward of 880 in number. In the United States of America the first act of Congress relating to lighthouses was passed in 1789, and there are now in American waters over 3,000 lights and light-ships and 246 fog-signals.

The early lighthouse towers had on their summits grates or chauffers, in which billets of wood or coal were burned, but though expensive to maintain—some of them using 400 tons

LIGHTHOUSE

of coal yearly—were uncertain in their appearance, varying with the ever-changing character of the atmosphere. Such coal-lights survived in Scotland till 1816, in England till 1822, and on the Baltic till 1846.

Construction.—The difficulties of building are very great, as may be judged from the following facts: Winstanley's Eddystone took four years to erect, and was finally swept away; Rudyerd's and also Smeaton's Eddystones took each three years, the Bell Rock took four years, the Skerryvore five, and Dhuheartach three and a half, the great difficulty being to effect a landing of men and material. At Minot's Ledge, off the Massachusetts coast, General Alexander got only 30 hours of work in the first year, and 157 in the second, and the histories of the Bell Rock, Skerryvore, Dhuheartach, Chickens, Eddystone, and some others tell the same tale. The cost of lighthouses may vary much; for instance, the Bell Rock cost \$310,000, Skerryvore, \$430,000; Spectacle Reef, on Lake Huron, \$300,000; and it will be easily seen that an ordinary land station, fully equipped, will cost much less—as a matter of fact, about \$25,000 to \$50,000. Light-vessels cost about \$45,000.

These towers are constructed of steel, or hard stone, such as granite, or cement-concrete faced with hard stone, and of such a mass and strength as to prevent their being overturned or destroyed by the waves. A typical stone lighthouse is built of granite, say 140 feet in height, with a diameter at the base of 42 feet and at the top of 16 feet, and contains 58,580 cubic feet, or about 4,308 tons of masonry. A staff of four light-keepers is attached to such rock lighthouses, three residing in the lighthouse and one on shore, the reliefs being fortnightly, so that each man has six weeks on the rock and two weeks ashore. At land lighthouse-stations, where women and children can be stationed, the keepers' families reside with them, and the staff consists of three men when there is a fog-signal, and two men when there is only the light to attend to. It is considered essential that a constant watch be kept in the light-room during darkness to ensure the proper exhibition of light.

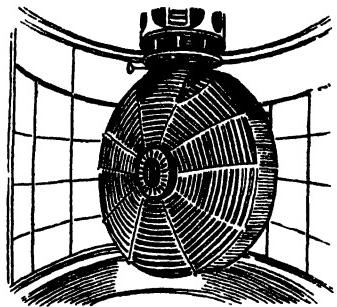

Optical Apparatus.—The object of using optical apparatus in a lighthouse is to direct, as far as possible, all the rays of light that proceed from the *radiant*, or source of light, so as to be visible only on the sea between the near sea and the sea horizon. In the Eddystone lighthouse, up to the commencement of the 19th century, the lighting apparatus consisted of a chandelier of tallow candles, though parabolic reflectors made of facets of silvered glass mirror, set in a mould of plaster of Paris, were introduced in 1768 and used in several lighthouses, the effect of these reflectors being to concentrate and throw seaward the rays of light from a flat-wick lamp placed in the focus. At a later date reflectors composed of sheet copper, plated with silver and formed into a parabolic curve, were largely introduced and are still in use. These reflectors, where a fixed light was desired, were arranged in two tiers on a frame, as many as 26 being necessary to show a light of equal power all around the horizon, and in the case of flashing lights seven were grouped on each of four faces of a frame that was

rotated by clockwork. This mode of lighting is termed *catoptric* or reflecting system. The method of building lenses of separate rings or prisms of glass, so as to form a larger lens than could be obtained from a mere bull's-eye formed of one piece of glass, was first adopted for lighthouses in 1822. For a fixed light the built-up lens was so arranged as to form a polygon with one burner in the focus, and for a flashing light annular lens panels were grouped round the one central burner and revolved by clockwork. In 1892 Charles A. Stevenson made the lenses spherical in form in the vertical plane, and in 1895, with great advantage to the power of the light, abolished the old section of the elements and gave them an equiangular section. This equiangular profile also permits of the refracting elements being extended to 80° of focal opening, and indeed farther, without loss of efficiency. The setting of lenses eccentrically has rendered possible a diminution in the diameter, and consequent saving in cost of lantern and tower. Besides the fixed-light apparatus and the lens panels many other forms of prisms for various purposes have been introduced. Thomas Stevenson's catadioptric mirror, formed of totally-reflecting prisms, and subsequently improved by James I. Chance, is largely used; and vertical straight prisms, placed in front of either fixed light or holophotal panels, are used to deviate the light azimuthally over particular arcs where the light is required. The desire to increase the power of the lights induced some lighthouse authorities to advocate the use of larger burners without increasing the focal distance of the apparatus, with the result that little advantage was gained, as most of the light was ex-focal. It was not, however, till 1885, that the first *hyper-radiant* lens was constructed, with the result that when tested it was found to produce a beam twice as intense as that from the previous lenses with the same large burners in the foci. This hyper-radiant lens is now largely used where great power is desired. See PLATE.

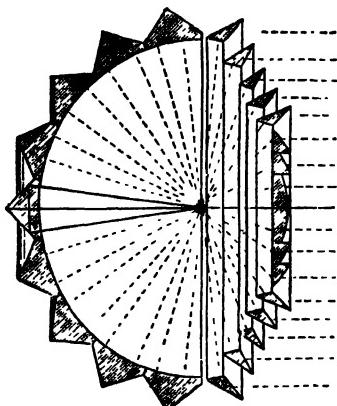

Radians.—The radians used in the focus of the apparatus in foreign lighthouses are generally 1-, 2-, 3-, 4-, 5-, 6-, or even 10-wick cylindrical paraffin burners, though gas burners, incandescent burners, and the electric light, both arc and incandescent, are also in use. The use of paraffin resulted in a large saving. The electric light is now generally used in the United States. The popular idea that the electric light is not so good in fog as oil or gas lights was confuted in 1885, when it was found that oil and gas were equally affected by atmospheric variations, that the electric arc light is absorbed more largely proportionately to its initial power by haze or fog than oil or gas lights, but that in all weathers and at all distances its penetrative power was found superior to the gas and oil lights, and that all three are nearly equally affected by rain. These results are confirmed by practical experience in our lighthouses.

Characteristics.—To enable the sailor to distinguish one lighthouse from another, lights in proximity to one another are arranged to exhibit different characters. The characters in common use are: fixed light; flashing light, showing one flash at regular intervals of a few seconds; group flashing lights, showing two or more

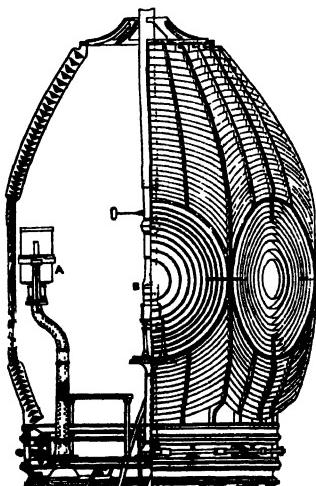

LIGHTHOUSE.

LIGHTHOUSE

flashes in quick succession, followed by a longer period of darkness than that which separates the flashes; occulting lights, which show a fixed light and are eclipsed for a few seconds at regular intervals. Colored lights, red and green, are also used with any of the foregoing characters to produce further distinctions, but in general only to mark danger arcs, or in conjunction with a white flash, as the tinted-glass shades interposed to produce the desired color seriously cut down the power of the light, and are not, unless of a very dark shade, easily distinguishable in foggy weather from a white light.

Machines.—To produce these various characters the lenses are placed on a carriage which revolves on conical rollers, or is floated in a mercury trough, and is driven round by clock-work actuated by a falling weight. The tendency has been in recent years to drive the apparatus faster, so as to make the period of phase of the light as short as possible. While this is a desirable object it involves at the same time shortening the duration of the flash on the eye of the sailor, to which there is obviously a limit, if distinct vision is to be obtained under practical conditions. A flash of about half a second in length is regarded as what should be aimed at. The light at Sandy Hook, N. J., is an example of the modern flashlight.

Lanterns.—The apparatus is placed in a glazed lantern erected on the top of the lighthouse tower. With the view of intercepting as little light as possible, the framing or sashes are made of as small sectional dimensions as is consistent with strength, and are made either diagonal, with diamond-shaped flat panes, or helical with curved panes. The upper part of the lantern is made dome-shaped with a ventilator to carry off the fumes from the lamp. The size of the lantern varies with that of the apparatus, the usual size for a first-class light being 12 feet in diameter and 10 feet height of glazing.

Lightships.—In certain situations, such as on rocks where there is not sufficient room to get a large enough base for a tower, or on sandbanks where the sand is liable to shift, it is impossible, except at a prohibitive cost, to erect towers to carry the light. In such situations recourse is had to mooring in the vicinity a vessel which carries the light on a mast. The light is generally shown from a lantern formed round the mast, and the apparatus consists of parabolic reflectors or small dioptric apparatus. These light-vessels have a crew consisting of a master, mate, and nine men.

Beacons and Buoys are used in situations where powerful lights, such as can be shown from lighthouses and lightships, are not necessary, and where the extinction of the light would cause inconvenience and not disaster, but where some guidance is desirable, as, for example, in narrow sounds, rivers, and estuaries. Beacons are now frequently lighted with small dioptric apparatus, the illuminant being either compressed oil-gas stored in a receiver, in which case they need no attention for six weeks, or with oil-burners, in which case they must be trimmed every three days. Buoys are made of various shapes to denote on which side of them the safe channel lies. Thus, can-shaped buoys,

those with a flat top, are to be passed on the port hand, and conical shaped buoys on the starboard hand when the ship is going up an estuary or with the flood-tide, and vice versa. Spherical buoys denote a middle danger which may be passed on either hand. Buoys for particular places are further differentiated by color and top marks.

Fog-signals.—During the prevalence of fog and snowstorms the most powerful lights are obscured, and it becomes necessary to guide the mariner by sound signals. Hence a fog-signal has become a necessary adjunct of a fully-equipped lighthouse station. Various instruments, such as bells, gongs, guns, steam-whistles, explosive charges of tonite, reed trumpets, and sirens sounded by steam, electricity, or compressed air, are used. The most efficient and powerful fog-signal is the siren sounded by compressed air. In spite of the recent improvements in fog-signals they are undoubtedly the weak point in coast protection, as the exact direction from which a sound is coming is not easy to locate, and owing to the capricious and uncertain range at which sound can be heard.

Administration.—In Great Britain, the Trinity House of London, the Irish Lighthouse Board, and the Northern Lighthouse Board are the lighthouse authorities. The two last named were not constituted till 1786, but the Trinity House may be said to have originated in 1514. The French Commission des Phares was constituted in 1792, and remodeled in 1811; the United States Lighthouse Board was formed in 1789, and reconstructed in 1852. In Sweden, Norway, Holland, Denmark, Russia, and Austria the lighthouse administration is under the Admiralty or minister of Marine. In Spain, the system of administration is similar to that of France. For American administration see the article **LIGHTHOUSE BOARD OF THE UNITED STATES**.

Progress in America.—From one of the poorest-lighted coasts, the American Atlantic seaboard has, within a quarter of a century, become one of the best in the world, and the new system of lighthouses and signal lights is far more comprehensive than anything heretofore attempted. The Cape Hatteras region, and the scarcely less important Cape Cod district, early received special attention. Both of these capes were in the direct route of commerce, and the storms and shoals that made them dangerous to navigators had to be offset by adequate lights which would warn mariners of their proximity. The first attempts at lighthouse construction were consequently made at a few such dangerous points along the coast, and from these in either direction new lights were gradually erected. They formed the beginning of the new system which seeks to make all of our coast so well protected that navigators need have little apprehension in approaching the land from any direction at any point. But the rapidly increasing commerce on both the Atlantic and Pacific seaboard has made in recent years a more comprehensive system of lighthouses imperative. Likewise the shipping interests of the Great Lakes, the Gulf of Mexico, and the great inland rivers, have multiplied in importance, and the need for better protection from dangers to navigation has been general. For a quarter of

LIGHTHOUSE BOARD — LIGHTNING AND LIGHTNING-RODS

a century now the American lighthouse system has expanded and developed, until it has reached a point in its evolution where it is without question one of the best in the world.

The full extent of the lighthouse service can best be appreciated by simply stating that there are some 9,000 warning lights and signals stretched along the American coasts, forming a perfect link so that the navigator need never be beyond the sight of one of the beacons. Of this grand total — including lighthouses of different classes, buoys, beacons, and danger signals — over 3,000 are lighted, giving forth their signals at night time. One thousand of these lights are located on the Atlantic coast, 1,500 are scattered along the rivers and inland waterways, 500 on the Great Lakes, and 200 on the Pacific coast. The so-called lighted "aids" include a great variety of modern inventions, from the tall flashlight lighthouse, with its base of steel and stone, and costly lamp operated by electric power, to the modern gas and electric-lighted buoys, beacons and lightships. The advances made in lighthouse and buoy construction represent some of the marvels of modern engineering science.

In 1903, the most important light in the United States, the great tower at Barnegat, N. J., was completed with a light equipment equal to 30,000,000 candle-power. Steam and power are generated for local use, for the heart of the light is a 6,000 candle-power arc light. This is intensified by a great lens built up of rims of prismatic glass, with a bull's-eye in the centre 18 inches in diameter. This monster light can be seen at a distance of 100 miles; but, taking the curvature of the globe into consideration, sailors can make it out while still over 20 miles away. The Barnegat station is a most important one, being located on the most easterly point of the dangerous low-lying Jersey coast. See PLATE.

In the matter of lightships the United States leads the world. More than 40 of these are stationed at points along our coast where beacons are necessary, but where the building of lighthouses is impracticable. The Diamond Shoal lightship warns the navigator of his approach to dreaded Cape Hatteras. For years the lighthouse board tried to build a lighthouse on Diamond shoal, but at last, after more than \$250,000 had been spent and several lives lost, the attempt was given up.

The Fire Island lightship is one of the line of ocean lampposts which mark the entrance to New York harbor. It is equipped with a steam engine, electric lights, a steam whistle and many other improvements. The new South Shoal lightship, which is anchored 26 miles off Nantucket, is farther from shore than any other lightship in the world. It is the first American outpost and guards a shoal which in times past was a veritable graveyard for ships.

Steel Tubular Structures.—One of the most noted advances in modern times has been the abandonment of the old towers of stone or brick and the adoption of the steel tubular structures in their places. The latter are built more easily on a solid, rocky foundation than the old huge piles of masonry. The steel skeleton is bolted into the solid rock or anchored there by means of long spindle-like legs, which

sink many feet down into the firm foundation. These huge cylindrical towers of steel withstand the pressure of wind far better than the stone and brick structures, and their strength is so great that there is practically no danger of their ever being seriously injured by the elements. Even where the lighthouses are built in the water to mark shoals or dangerous reefs, the steel tubular style of structure is adopted. The foundation work of the structure is built up above the water with stone or concrete, and to this the steel tower is bolted. The latter looks more like a giant smokestack than anything else, and its stands as a permanent beacon of the sea to warn mariners of their danger. Not only is additional strength and security obtained through the adoption of the steel tubular lighthouses, but the cost of construction is greatly reduced. Modern lighthouses cost far more than they did in former days, but that is due to the fact that they are built on a larger and more enduring scale, and the lights are of far greater power and intensity. A modern American lighthouse frequently costs \$125,000, and often one third of this is spent in the electric light and apparatus alone. In the old system the lights represented a comparatively small proportion of the expense.

Editorial Staff, 'Encyclopedia Americana.'

Lighthouse Board of the United States. The, was organized in 1852 by Act of Congress, and has the management of all lighthouses, beacons, buoys, lights, etc. The board is composed of two naval officers, two engineers, and two civilians of scientific attainment. The Secretary of the Treasury is *ex-officio* president, while a chairman is annually elected from the Board. Standing committees are appointed on "experiments," "lighting," "engineering," "finance," and "floating aids to navigation."

Lightning and Lightning-rods. Franklin in 1751 proved that lightning is merely a vast electric spark; and until a generation ago, little was added to his exposition, to define the differentia of this special variety. The origin of atmospheric electricity is believed to be simple friction. Faraday showed that a powerful current could be excited by steam-driven spray against a water surface, and the friction of wind-driven mist on the earth's surface may produce a great difference of potential between the latter and the upper air, possibly though not probably assisted by the friction on dust particles in the air. In any event, rain conducts a portion of it to earth; so that a period of dry weather causes a great accumulation of electricity, the particles of air distributing their charges through each other. This would make the earth and sky, in Lodge's comparison, the two coatings of a Leyden jar, but ordinarily the distance is too great for a spark to pass. The effect of electrical discharges on vapor, however, is to condense it into larger globules; this causes it to sink toward the earth as cloud, and the enormous tension relieves itself by pass-

LIGHTNING AND LIGHTNING-RODS

ing to the earth or objects upon it, preferably projections of some height. If conduction through the cloud were instantaneous, it would be drained of its charge in one immense flash; but it being a poor conductor, several flashes at different points are requisite.

The discharge is determined by the tension of the air, the maximum of which without rupture is $\frac{1}{2}$ gramme per square centimetre. If the rupture is local, there is no flash, but only a brush; but it is often the case that when the weakest spot has given way, a general breach follows for a long distance, sometimes miles, creating the flashes which pass either from cloud to earth or from cloud to cloud; and as the discharge of this portion draws the remaining current toward it, a second flash or set of flashes is made probable. But this analysis shows what experiment proves, that this flash is not a single discharge, but the successive discharges of a countless number of vapor particles or raindrops toward the earth or other electrified particles in the air, with such rapidity of progress that they seem simultaneous; since it is most improbable that if vast numbers of points gave way at once, they should all give way in the same line. It has been further proved by Prof. Ogden N. Rood that even so, the flash is not a single sequence merely too swift for the eye to individualize; but although it lasts only a fraction of a second, it is itself composed of primary flashes in irregular sequence, each lasting but from a thousandth to a few thousandths of a second. This result was obtained by photography, which has invaluable supplemented laboratory experiment. By the latter, Prof. John Trowbridge has formed artificial flashes of lightning many feet long, made up of a combination of small discharges from a great number of petty cells. It had been long before proved by Joseph Henry that every electric discharge is an alternating or oscillating current, the periods of oscillation being only a few millionths of a second each and diminishing very rapidly in intensity; the entire duration depending on the magnitude and distance of the bodies. Hence it has been inferred that the small primary flashes are instances of these alternating discharges. Photography steadily tends to confirm these views.

Lightning according to its manifestations is divided into three classes. The "flash" or "stroke" lightning is the one had in mind when the name is used without qualification; it occurs either as a sharp zigzag line of extreme brilliancy, or the same forked, or in a wavy line oscillating with enormous rapidity, or in tree shapes with endless branches, or ribbon shape, or in a mass of strands of close but distinct parallel flashes like unraveled rope, or still other shapes. Dark flashes in photographs are only photo-chemical decompositions on the plate. The second sort is sheet lightning, a sudden glow of a golden or reddish tinge on the horizon, with no definite shape or bounds. It is not usually an actual discharge in that form, the very genesis of lightning making it rare; but is the reflection of lightning flashes out of sight beyond the horizon, cast on the clouds or atmospheric haze, and visible sometimes for many scores of miles beyond the place of the actual storm which causes the flashes. A third is ball lightning, which for a long time was not admitted as a genuine form of electric discharge, and is still a very difficult and in some points

unexplainable phenomenon. It has not been photographed, though something like it has been produced on a small scale in the laboratory. It is described as a ball or globe of brilliant light moving slowly a short distance above the surface of the earth or even rolling upon it, and has been said on occasion to float through an open door or window into a house, as though drawn in by a draft of air; it usually explodes, but without doing much damage. Under the head of lightning is sometimes included Saint Elmo's fire or corposant,—jets and brushes of light seen not only at the tips of masts and yards of a ship in a thunderstorm, but on mountain tops, in hissing tongues of brilliant white and blue light several inches long.

The rope-strand lightning is not solidly accounted for; though there is general agreement that the first flash makes a rent or tube in the air, along which succeeding discharges rush back and forward. Of the multiple flash, the explanation most conformable to laboratory experiment—where a spark between electrodes has been made to assume a like shape by blowing across it—is that the tube does not close for a fraction of a second, and the wind always violently present in a thunderstorm moves the mass of air sidewise simultaneously enough to keep the tube intact for a moment. Another theory holds that the tube closes up too quickly for this, but is so large that the alternate flashes appear side by side.

The thunder and the large raindrops accompanying lightning are well understood. The heat produced by the electric discharge traversing the atmosphere causes a sudden expansion of the particles next it, with a sharp compression of those beyond, in a great wave; on its passage the particles contract as suddenly, and the waves roll violently back, producing the noise of thunder. From the relatively slow passage of sound in the air, and the increased and uneven refraction due to differences of temperature and wind movement, the thunder-waves very soon begin to rise and pass inaudibly overhead; so that it is rarely heard more than fifteen or twenty miles off. The consolidation of the vapor into drops has been exactly imitated in the laboratory by electrifying spray, which causes the mist particles at once to begin aggregating in large globules. It has been shown that the mutual repellence of particles ceases as soon as a difference of potential is established by electrification, which substitutes a sort of suction around centres of force.

Protection from Lightning.—The annual destruction of life and property by lightning is very considerable: the former cannot be prevented to any great extent—though common-sense as to exposure can be instilled,—the latter could in part. In the United States during 1900, 713 persons were killed; parts of the Rockies and the upper Missouri Valley were the most dangerous. This rate, about five per million, is larger than in other countries, from our great population of outdoor agricultural and ranching laborers. Fatalities are everywhere increased by the tendency to seek shelter from the rain when caught out in a storm; and these isolated shelters, as trees, barns, monument buildings in public parks, etc., are among the most liable to be struck. In the same year, 1,842 domestic animals were killed; barbed-wire fences are held blamable to a large extent, from the animals'

LIGHTNING ARRESTER — LIGHTNING-STROKE

habit of huddling in fence corners during a storm. Statistics of buildings struck are in some respect significant, in others not detailed enough for utility. Thus, in Schleswig-Holstein during 1874-83, the annual average of strokes for wooden and thatched roofs was nearly $2\frac{1}{2}$ times greater than for slate or metal roofs, that for chimneys over 16 times as many even as the former, and that for windmills over one third larger still. On the other hand, we learn nothing from the fact that in the United States during 1900, out of 1,847 buildings struck, 40 had lightning-rods, 855 had not, and there is no report of 952, because not knowing what proportion of all buildings had them,—probably a very small one,—we have no percentages. On the other hand, it is notable that in nine years ending 1892, 2,335 barns, 104 churches, and 664 dwellings were struck, and the larger fire-insurance companies have generally ceased insuring farm buildings. Isolated buildings in general were in five times as great danger as those in city blocks, perhaps partly because protected by metal cornices, etc.

But is it worth while attempting to protect buildings in general from lightning? Aside from the fact that we are never sure a building struck may not involve a loss of life, the matter resolves itself into a question of cost, and it must be said plainly that it is not worth while. The problem is one for the insurance companies. In the eight years, 1885-92, in the United States, there were 3,516 fires from lightning, with a loss of \$12,663,835, or a little over \$1,500,000 a year. The insurable part of this was nearly all insured, and the practical question for property-holders is whether lightning-rods secure lower rates. Notoriously, they do not. The companies make not the least difference in rates for "protected" buildings, as to insurability or rates, and the officials rarely put them on their own dwellings; the lightning-rod business is virtually extinct in this country. The public would therefore gain nothing by the outlay; except that with uninsurable buildings, it would probably pay to enmesh them with metal points rather than undergo the risk. Of course also there are many cases where even a heavy expense ought to be incurred, as with buildings or their contents not replaceable with money,—historic or noted architectural structures, museums, etc. But the fact remains that to reduce this \$1,500,000 to one third that amount would cost fifty times the saving in gross and several times the amount in yearly interest.

If protection is desired, however, it is fully proved that a great quantity of scattered metal points—whether iron or copper is immaterial, and iron is cheaper—is the most effective; a mesh of barbed-wire fence over the roof and chimneys would be not only the cheapest, but one of the most effective protections. Perfect safety would be obtained by enclosing the building in a metal sheath, as no electric discharge can penetrate into an enclosed metal safe; next to this, a closely meshed wire cage; next a number of metal rods or wires all around. One rod is of little moment. Bulk of rod is of no avail, because the flash is so sudden that the interior or core of the rod has no chance to operate, all the discharge passing back and forth along the "skin"; but as the latter is liable to corrosion, the wire should not be too thin. The heavy copper rods of old time, however, are not

regarded as useful. Nor can any rods or wires ensure absolute protection. The old "conduit" theory of draining off the lightning, and having a good conductor to prevent resistance and insulators to prevent jumping, is now discarded: it is recognized that there is an enormous amount of electric energy to be discharged almost instantly, it is almost certain to distribute itself around a considerable area, and all that the points can do is to insure and regulate that distribution. There should always be a good "ground" or "earth" at the bottom, as a ton of coke or a water ditch. Consult Lodge's 'Lightning Conductors and Lightning Guards,' 1892.

Lightning Arrester, in telegraphy, a contrivance for guarding against passage of atmospheric electricity through the instruments. The line wires are attached to a plate of brass, usually serrated on the under side. This plate rests on another plate connected with the ground, the two being separated by a thin layer of insulating material.

Lightning-stroke. The effects of lightning-stroke on the body resemble those produced by large amounts of electricity at high voltage. Persons subjected to the influence of lightning-stroke may suffer very slightly or may be killed, and between these extremes a vast variety of minor or major injuries may result. The most characteristic form of injury is some sort of burn. This occasionally shows on the skin as an arborescence, which was formerly thought to resemble the tree under which a patient had sought shelter during a storm, but is, of course, solely an effect of the zig-zagging of the electrical discharge. In many persons mental shock and prolonged nervousness are frequent symptoms. Mild stunning, with a sense of suffocation, may be experienced when an electrical bolt strikes near a person, and occasionally nervous and hysterical attacks are induced. Suppression of menstruation and abortion have been reported. Numbness and prickling of various areas of the body; paralysis of the muscles; deafness; loss of smell and taste; and paralysis of the bladder and rectum have all been described. Occasionally insanities follow lightning-stroke. The experiences of persons who have been exposed vary greatly; but flashing in the eyes, buzzing in the ears, general tremor, which may go on to convulsions, with or without loss of consciousness, are not uncommon, and people who have been seen in this stage have been described as being blue, with muscles tightly contracted, the pupils dilated, the breath deep and snoring, and pulse feeble.

In death by lightning, changes in the nervous system have been found, and it is probable that the cause of death may be either the result of minute hemorrhages, which take place in the important centres of breathing and of the heart-action and in the medulla; or death may be the physiological effect of the electricity on the heart, causing a form of heart-tetanus, with rapid cessation of the movement of this organ.

The treatment of lightning-stroke, as well as of other forms of electrical injuries, should be promptly instituted. If commercial currents are used they should be removed at once, care being taken to use insulating materials to remove live wires. External heat to the body with hot-

LIGHTON—LILIACEÆ

water bottle, cardiac stimulation with whiskey, ammonia, etc., with artificial respiration, should be simultaneously used.

No method of artificial respiration or other attempt to produce consciousness should be abandoned under three to six hours, as often no signs of life may be brought out in less than two to three hours. It is seriously advised by some observers that, before giving up all hope, an injection of an alkaline solution into the blood should be used. Hot saline solution may be thrown into the rectum, and the treatment should be continued until all possible methods of resuscitation have been employed. Consult Jelliffe, 'Death by Lightning and Electricity' (in 'Text-book of Legal Medicine and Toxicology,' 1903).

Lighton, William Rheem, American prose writer: b. Lycoming County, Pa., 13 July 1866. He was admitted to the Kansas and Nebraska bar in 1891 and has published 'Sons of Strength: a Romance of the Kansas Border Wars' (1899); 'Lewis and Clark,' in 'River-side Biography' Series.

Lig'nin, the substance of wood-fibre, formed in part at least by conversion from cellulose (q.v.), and contained within the cellular tissue, giving hardness and weight to the woody parts of plants. Its chemical composition is not determined, but it is characterized by being soluble in weak alkalis and insoluble in water.

Lig'nite, a partially carbonized fossil wood, retaining its woody fibre, and intermediate in its qualities between peat and coal. It is found in the secondary and tertiary strata, but chiefly in the latter. For description of lignite, and especially for composition of American lignites, see COAL.

Lig'num Vitæ, vi'tē. See GUAIACUM.

Ligny, lēn'yē, Belgium, village, 14 miles northwest of Namur, celebrated by the defeat of the Prussians under Blücher by the French under Napoleon, 16 June 1815, the same day on which Ney's command was engaged with the British under Wellington at Quatre-Bras. The Prussians lost 12,000 men and 21 cannon; the French, 7,000 men.

Liguori, lē-gwō'rē, Saint Alfonso Maria de, Catholic prelate, founder of the religious order called Redemptorists: b. Naples 26 Sept. 1696; d. Nocera, Italy, 1 Aug. 1787. He was originally a lawyer, but became a priest in 1722, joined the Congregation for the Propagation of the Faith, instituted in Naples, and occupied himself as a missionary in the instruction of the ignorant peasantry. In 1732 he founded a monastery at Villa Sella, the members of which were called the Order of the Most Holy Redeemer and were to be employed in the instruction of the people. This order, approved of by Pope Benedict XIV. in 1749, rapidly extended in Italy, Germany, Spain, and France. Liguori was in 1762 appointed bishop of Santa Agata de' Gotici by Clement XIII., from which office he resigned in 1775. He was canonized in 1839, and in 1871 was declared a doctor of the Church. His 'Theologia Moralis' has appeared in several recent editions (Ratisbon, 1881; Turin, 1892; Genoa, 1898), and there is a German edition of his letters (Ratisbon, 1893, et seq.).

Liguria, lī-gū'rī-a, in ancient Greek and Roman geography that portion of northern Italy extending along the Mediterranean from the frontiers of Gallia Cisalpina to those of Etruria, bounded on the north by the Po, east by the Macra, and west by the Varus. These were its limits at the time of Augustus, but at an earlier period it extended to the borders of Gaul, or even to the mouths of the Rhone. In 1797 Genoa received from Napoleon I. a democratic constitution, under the appellation of the Ligurian Republic. This republic ceased to exist in 1805, when the emperor incorporated it with France. After 1814 it formed part of the kingdom of Sardinia, and now of that of Italy, in which it comprises the provinces of Genoa and Porto Maurizio.

Ligu'rian Republic. See LIGURIA.

Lija, a fish. See FILE-FISHES.

Lilac, a genus of ornamental deciduous shrubs and trees (*Syringa*) of the order *Oleaceæ*. The species are characterized by opposite slender-stalked leaves, and purplish or white usually fragrant flowers in erect panicles. Nearly all the species, which have developed many horticultural varieties, are valued for park and garden planting, on account of their hardiness and free-blooming qualities. The common lilac (*S. vulgaris*) is a native of southwestern Asia, whence it was taken to Vienna during the closing years of the 16th century. It is probably the most widely planted of all the species. The wood of its larger specimens, which sometimes attain heights of more than 20 feet, is valued by cabinet makers, for turning and inlaying. About a dozen species are cultivated in America. They do best in deep, rich soil, but will succeed almost anywhere; indeed, they are likely to become a nuisance from their habit of suckering, a habit taken advantage of for propagating purposes. Cuttings are also used, and some of the newer and choicer varieties are grafted upon ordinary lilac or upon privet stocks. During the closing years of the last century the plant came into vogue as a florists' flower, large quantities being forced for the winter and early spring markets.

Lilburne, līl'bērn, John, English sectary and political agitator: b. Thickney Puncharden, County Durham, about 1614; d. Eltham, Kent, 29 Aug. 1657. For putting forth tracts hostile to the Anglican Church he was whipped and imprisoned in 1637, but was released by the Long Parliament in 1640, and the conviction having been declared illegal and tyrannic, he received \$15,000 indemnity. He then joined the army, and rose to the rank of lieutenant-colonel. He was one of the party known as the "Levelers" (q.v.), and for his attacks on Cromwell and others was several times committed to the Tower. Having been exiled and having returned without leave, he was put in prison and tried for his life, when he was acquitted but not liberated for some time. Subsequently he became a member of the Society of Friends. Hume describes him as "the most turbulent, but also the most upright and courageous of men."

Liliaceæ, līl-i-ā'sē-ē, or **Lily Family**, one of the most important orders of plants because of the uses made by man of many of its species, about 2,500 of which are comprised in nearly 200 genera. The characteristics of the group are

LILIENTHAL—LILLO

monocotyledonous seeds; usually herbaceous stems which arise from bulbous, tuberous or rarely fibrous roots; generally narrow, simple leaves; and six-parted or toothed flowers solitary or arranged in various ways, such as panicles, racemes, etc. In habit, many are adapted to deserts, some to ponds and streams, others are climbers, etc. Among those useful for food may be mentioned asparagus, onion, garlic, leek, chive, rocambole, shallot, camass and various species of lilies. A very large number of species are used for ornament; for example, lily, hyacinth, tulip, fritillary, lily-of-the-valley, tuberose, Allium, and Yucca. Several species of Xanthorea and Dracena yield useful resins; some of the genus Chloragalum furnish a substitute for soap; and certain species of Yucca, Sanseveria, and of other genera, yield valuable fibres. Isolated species of various genera have been used in medicine.

Lil'ienthal, Max, American rabbi: b. Munich, Bavaria, 15 Nov. 1815; d. Cincinnati, Ohio, 5 April 1882. Graduating from the university of his birthplace, he was called to the directorship of a Hebrew school in Riga, Russia, and at government expense traveled through the 17 western provinces of Russia to encourage the Jews to make educational reforms. In 1842 this mission was ended, and until 1845 he remained in St. Petersburg, perfecting his educational system, when the Czar Nicholas issuing orders which aimed at the conversion of the Jews to the Greek Church, he emigrated to America. On his arrival in 1844 he was made rabbi of three synagogues, but in 1850 resigned to establish a school. In 1855 he accepted a call as rabbi of the B'nai Israel Congregation of Cincinnati, a position he held until his death. He was foremost in civil and educational reform, an active member of the board of education, and a director of the Cincinnati University. He was prominent in the councils of the Free Religion Associations, and always championed the cause of progressive Indians with his voice and pen. He aided largely in the establishing of the Hebrew Union College, and as an orator did much in his addresses in churches and on the public platform to promote social and religious reform.

Lil'is, or Lilith, a character in Jewish mythology. The Talmudists say that Adam had a wife before Eve, whose name was Lili. Refusing to submit to Adam, she left Paradise for a region of the air. She still haunts the night as a spectre, and is especially hostile to newborn infants. Some superstitious Jews still put in the chamber occupied by their wives four coins, with labels on which the names of Adam and Eve are inscribed, with the words "Avault thee, Lilith!" Our word "lullaby" is said to be a corruption of "Lilla, abi" (Lilith, avaunt).

Liliuokalani, lē-lē-wō-kā-lā'nē, Lydia Kamekeha, kā-mā-kā'hā, ex-queen of Hawaii: b. Honolulu 2 Sept. 1838. She was a sister of King Kalakaua, and succeeded him in 1891. She was married to John O. Dominis, an American (d. 1891), who became governor of Oahu. She attempted to substitute a less liberal constitution for that of 1887, and this course resulted in her being deposed 30 Jan. 1893. The islanders then adopted a provisional government, which soon became a republic. She endeavored

to secure assistance from the United States, visiting Washington in 1896 for that purpose, but on the annexation of Hawaii to the United States, in 1898, returned to the island. She revisited the United States in the winter of 1901-2 to press her claims for indemnity on the crown lands. See HAWAII.

Lille, lē'l, France, an important town, capital of the department of the Nord and chief fortress of the north, 127 miles north of Paris, and 7 miles from the frontier of Belgium. The former capital of French Flanders it was fortified as early as 1007. It is well built, and has spacious, regular streets, lined with large, massive houses. In the northwest of the town stands the citadel, a masterpiece of Vauban. New fortifications include a circle of detached forts. Among the churches are: St. Maurice, in the flamboyant style, recently restored; Notre Dame de la Treille, in 13th century Gothic; St. Catherine; the Madelaine; and the Protestant Church. Among secular buildings are the Hôtel de Ville, with rich collections of pictures, drawings, etc.; the exchange (1652); the prefecture; the palace of justice; the arsenal; the Paris Gate, a triumphal arch in honor of Louis XIV.; the general hospital; the theatre; and the concert-hall. Lille possesses a state university with four "faculties," a Roman Catholic university, lyceum, communal college, school of art, conservatory of music, public library of 100,000 volumes, botanic garden, zoological garden, etc. The industries include cotton spinning and weaving, fine linen thread, linen and cotton twist, broadcloth, beet-sugar (raw and refined), soap, oil, ribbons, tulles, tobacco-factories, engine-works, foundries, dye-works, bleach-fields, breweries and distilleries. Its situation on the frontier and extensive railway and water communication, make Lille a great entrepôt of trade. Pop. (1901) 215,431.

Lillibullero, lil'i-bū-lē'rō, a political ballad that "sung James II. out of three kingdoms." A scurrilous attack on the Irish recruits, it is said to have been written by Lord Wharton in 1686, and the setting is ascribed to Henry Purcell.

Lillie, Arthur, English author. He went to India and served in the Bengal infantry 1847-63. He has published: 'Out of the Meshes,' a novel (1869); 'Buddha and Early Buddhism' (1881); 'Buddhism in Christendom' (1887); 'The Influence of Buddhism on Primitive Christianity' (1893); 'Madam Blavatsky and her Theosophy' (1895); 'Buddha and Buddhism' (1900); etc.

Lillie, Lucy Cecil White, American writer of juvenile and other books: b. New York 1855. Among her many works are: 'Prudence,' a novel (1882); 'Rolf House' (1886); 'The Colonel's Money' (1888); 'The Squire's Daughter' (1891); 'Alison's Adventures' (1895); 'Honest Endeavor'; 'Kenyon's Wife.'

Lilliput, lil'i-püt, the name of a fabulous kingdom described by Jonathan Swift (q.v.) in 'Gulliver's Travels,' of which the inhabitants are not greater in size than a man's finger.

Lillo, lil'o, George, English dramatist: b. London 4 Feb. 1693; d. there 3 Sept. 1739. The son of a Dutch jeweler, he was brought up to his father's trade, and was for several years in partnership with him. 'Silvia, or the Coun-

LILLY—LILY

try Burial' (1730), a ballad opera, was his first piece; and was followed (1731) by the famous 'London Merchant, or the History of George Barnwell,' nowadays better known by its subtitle, which made its author famous, and held the stage for nearly a century. It had a marked influence in its day, and may be regarded as a precursor of the "domestic drama." His other dramatic productions include: 'Britannia, or the Royal Lovers' (1734); 'Fatal Curiosity' (1736); 'Arden of Feversham,' an adaptation of an Elizabethan play, revised or completed by John Hoadly after Lillo's death.

Lilly, lili', William, English astrologer: b. Diseworth, Leicestershire, 1 May 1602; d. Horsham, Surrey, 9 June, 1681. In 1632 he became interested in astrology, and two years later was associated with others in an unsuccessful search for treasure in the cloisters of Westminster Abbey. In 1644 he published the first volume of his almanac, 'Merlinus Anglicus Junior, the English Merlin Revived, or a Mathematical Prediction upon the Affairs of the English Commonwealth,' which appeared annually till his death. The king of Sweden sent him a gold chain and medal in 1659 in recognition of a favorable horoscope cast for him a short time before. He published many works, and was frequently engaged in controversy. His chief writings are: 'Christian Astrology, modestly treated in Three Books' (1647), reprinted in 1852 by Zadkiel as 'An Introduction to Astrology'; 'An Astrological Prediction of the Occurrences in England for the Years 1648, 1649, 1650' (1648); 'Monarchy and No Monarchy' (1651); 'True History of King James I. and King Charles I.' (1651); 'Annus Tenebrosus' (1652); 'Anima Astrologiae' (1676); and 'Catastrophe Mundi' (1683). Butler satirizes Lilly in Hudibras under the name of Sidrophel. His autobiography was published in 1715.

Lilly, William Samuel, English controversial writer: b. Fifehead, Dorsetshire, 10 July 1840. He was educated at Cambridge and has been secretary to the Catholic Union of Great Britain from 1874. He is a champion of the Roman Catholic point of view in such works as 'Ancient Religion and Modern Thought' (1884); and 'The Claims of Christianity' (1894). Other works of his are: 'A Century of Revolution' (1899); 'First Principles in Politics' (1899); 'Essays and Speeches' (1897); 'A Year of Life' (1900); 'Renaissance Types' (1901); 'India and Its Problems' (1902).

Lily. The type genus (*Lilium*) of the order *Liliaceæ* (q.v.). The several hundred well marked species which have been described are succulent herbs with scaly bulbs and usually leafy upright stems terminated by solitary or variously grouped six-segmented flowers of very diverse colors and markings. In general, lilies are among the most popular of garden flowers, having held this position for centuries. But in the United States they have not taken the high rank that they hold in Europe, especially in Great Britain. This is probably due largely to the dryer, hotter climate, and the injudicious planting of the bulbs where they cannot long survive.

The various species and their varieties are adapted to a wide range of soils, a few, such as *L. tigrinum*, *L. canadense*, and *L. superbum*,

often succeeding in heavy land if well drained, and some, such as *L. washingtonianum*, *L. philadelphicum* and *L. concolor* notwithstanding the peculiar conditions of slaty ridges if deeply planted and well mulched during the growing season. But the greater number thrive best upon fairly rich, well drained, deep sandy loam, especially if sheltered from prevailing winds and the hot sun of midsummer. Not that the stems cannot stand sunlight; but the bulbs and roots should be cool and well but not excessively supplied with moisture and food. The bulbs should always be planted deeply, six inches or more, and the soil stirred to double the depth of planting. This not only assists in keeping the roots cool but protects the bulbs from excessive freezing, which seems to have some effect upon the vitality of shallow planted specimens of even the hardiest species. Since vitality is also impaired by the exposure of the bulbs to the air, great care should be taken in transplanting to place the bulbs back in the soil as soon as possible after their removal. Transplanting is best done in early spring, the clumps being dug up, divided, the large bulbs planted in new, permanent quarters and the small ones and the bulb scales in nursery beds, where they should remain from one to three years, according to size when planted and to the species. One reason why bulbs obtained from seedsmen fail is because of undue drying. Orders for lilies should be given before the seedsman can obtain the bulbs, and they should be filled by him without delay after the bulbs arrive. Often bulbs become so flabby from loss of moisture that they may fail to grow until the second year. Hence it is advisable to plant all but plump and turgid bulbs in a nursery bed, or where they may remain undisturbed for a year or two before being placed in permanent quarters. Propagation by means of seeds is slow in most cases; and many species rarely produce seeds in the United States.

The Bermuda Easter lily (*L. longiflorum*, var. *eximium*) is the only kind that is forced upon a commercial scale in the United States, though several other kinds are to be found in the principal florists' stores and in private conservatories. For forcing, the bulbs of this variety are planted as soon after their arrival from Bermuda as possible, generally before the end of September, and are kept in a cool dark place until roots are well developed and the tops commence to form, when they are brought into the light, and by judicious management of heat, are hastened or retarded to ensure their blossoming at desired seasons, especially Easter Sunday. The management of other varieties used in greenhouses is more or less closely similar.

In general, lilies are most effective when mixed in small masses among shrubbery and hardy flower borders, the various kinds being sufficiently separated either in distance between the groups, or in season of blossoming, to avoid the clashing of inharmonious colors. Many of them have been used thus for ornamental planting, but though the great majority are well worth growing, scarcely a dozen have become widely popular in the United States, and of these not one is a native American species.

The following are probably the best known species: Tiger lily (*L. tigrinum*), a Japanese species, often exceeds three feet in height and bears a loose raceme of sometimes a dozen nod-

LILY-OF-THE-VALLEY—LIMA

ding dark-red, purplish-spotted flowers. It is a very hardy, useful species for the border, where it does best in masses. Madonna lily (*L. candidum*), a native of southern Europe, often attains three feet, bears from half a dozen to two dozen large pure white fragrant flowers in a raceme. It is a highly ornamental species, will do well upon sandy soils and in full sunlight. The Siberian coral lily (*L. tenuifolium*), which seldom exceeds two feet in height, bears from one to a score of scarlet, nodding flowers. Being very easy to propagate from seeds and bulb scales and of simplest culture, it is especially popular with beginners. Gold banded or Japan lily (*L. auratum*), which sometimes attains four feet, bears a few yellow-banded, purple-spotted, white flowers in a short raceme. It is less persistent than the tiger, and the showy lily, and somewhat less easy to cultivate, but is particularly useful for planting among groups of dark colored shrubbery. Showy lily (*L. speciosum*), a Japanese species, often exceeds three feet, bears six or more white or pinkish, red-dotted flowers in a raceme. It is a specially hardy, thrifty and satisfactory species, both for out-of-door planting and for greenhouse use. Next to the Bermuda Easter lily and *L. longiflorum* it is probably more widely grown by florists for cutting than any other kind. It has both white and red varieties. *L. longiflorum*, the original species of the Bermuda Easter lily, is forced in the same way as its variety. It is a native of Japan, from which country most of the bulbs are imported.

Besides the species mentioned the following are considered worthy of wide popularity: *L. chalcedonicum*, *elegans*, *testaceum*, *maximowiczii*, *martagon*, *maculatum*, *henryi*, *monodelphum* and *superbum*. These do well with little care upon ordinary light loamy soils. *L. canadense* and *superbum* succeed upon the same soils but require rather shady places. For cold climates even as far north as Ottawa, Canada, the following have proved successful: *L. brownii*, *wallacei*, *citrinum*, *croceum*, *melpomene*, *pardalinum*, *pomponium*, *dahuricum* and *batmanniae*. The odors of *L. croceum* and *pomponium* are very offensive even in the garden, and when they are planted they should be at some distance from the house. Among the most fragrant are *L. longiflorum*, *auratum*, *candidum* and varieties. Consult: Bailey, 'Cyclopedia of American Horticulture' 1900-2; Elwes, 'A Monograph of the Genus *Lilium*', 1880; 'Botanical Gazette,' Vol. XXVII., p. 235 (1899).

Lily-of-the-Valley, a low-growing perennial herb (*Convallaria majalis*) of the lily family, with creeping rootstocks from which ascend radical leaves and little white or pink fragrant flowers arranged in racemes upon scapes. The plant being a native of western Asia is one of those popularly supposed to be referred to in the Sermon of the Mount, the tulip being another. The plants are perfectly hardy. They thrive in partially shaded fairly rich loam, and may be readily propagated by means of the underground parts. Since beds are apt to run out they should be renewed every few years. The strong terminal buds known as pips are extensively used by florists for forcing the flowers throughout the year. Several horticultural varieties have been produced, some with variegated or striped foliage, others with pink, varie-

gated or double flowers. A highly esteemed perfume, *eau d'or*, is made in France from the flowers; and the rootstocks have been used by druggists, but are less popular than formerly.

Lilybæum, *lil-l-bē'üm*, the ancient name of Cape Boeo (q.v.).

Lima, *lī'mā*, Ohio, city, county-seat of Allen County; on the Ottawa River, and on the Erie, the Pennsylvania, the Cincinnati, H. & D., the Detroit Southern and the Lake Erie & W.R.R.'s; about 70 miles north of Dayton and the same distance south of Toledo. It is situated in an agricultural region and in the natural gas and petroleum belt of the State. The oil fields extend into six counties in the northwestern part of the State. The chief industrial establishments are locomotive and car works, machine-shops, petroleum refineries, and railroad shops. The shipping trade is chiefly in petroleum, farm and dairy products, and railroad car equipments. The city is the seat of Lima College, opened in 1893 under the auspices of the Lutherans. The city owns and operates the waterworks. Pop. (1890) 15,981; (1900) 21,723.

Lima, *lē'mā*, Peru, South America, a department in the western part, on the Pacific Ocean; area, 13,310 square miles. It is mountainous in the east, but along the coast the land is low, and in the river valleys productive. A number of villages and towns are in the valleys. One of the principal agricultural productions is sugar. There are rich mineral deposits, but as yet the mines are undeveloped. Pop. about 300,000.

Lima, Peru, South America, city, capital of the department of Lima; on the Rimac River, seven miles from the Pacific. Callao, on the Pacific, at the mouth of the Rimac, is the port of Lima; it is connected with Lima by two railroads, one on each side of the Rimac. Another railroad extends from Lima to Concepcion, a town on the eastern slope of the Andes. This railroad is in one place 15,000 feet above the sea. The city was founded by Francisco Pizarro 1535, and named *Ciudad de los Reyes*, "City of the Kings," because the site was chosen on 6 January, the feast of the "Wise Men," or the "Three Kings." Lima has considerable manufacturing industries and is developing rapidly. The adobe walls which surrounded the city were destroyed in 1870, and boulevards made in their place. The city has long been famed for its educational institutions; the national university, chartered in 1551, is the oldest university in America. It has courses in theology, law, medicine, applied science, political science, art, and music. The national library, founded in 1822, with some books from older libraries, was destroyed in 1880 by the Chileans. It contained then 60,000 volumes. It now contains about 50,000 volumes. There are several other libraries in the city. There are several technical schools, professional, classical, naval, and military, and about 100 elementary schools, besides a number of small private schools. Several scientific and literary societies provide public lecture courses. The city is noted for being the home of the first American canonized by the Roman Catholic Church, Saint Rose of Lima (1586). It has frequently suffered from earthquakes, the most destructive of which any record exists occurred in October 1746. At the time of the war between Peru and

LIMA E SILVA—LIME

Chile, the city capitulated without any resistance, and the Chileans kept possession for two years. Pop. about 116,000. Consult: Mortimer, 'Peru'; Middendorf, 'Peru.'

Lima e Silva, Luiz Alves de, 100'ës ál'ves dã 16'mã è sél'vã, duke of Caxias, Brazilian soldier and politician: b. Rio de Janeiro 25 Aug. 1803; d. Santa Monica, province of Rio de Janeiro, 7 May 1880. He rose to the rank of brigadier in the Brazilian army, was successively president of Maranhão, vice-president and military commandant of São Paulo, and president of Rio Grande do Sul; and in 1851-2 was commander of the Brazilian army, which, with Urquiza, defeated the dictator Rosas at Monte Caseros and drove him from Buenos Ayres. In 1855 he became minister of war; and from 3 Sept. 1856 to 3 May 1857 and again from 3 March 1861 to 4 May 1862 was prime-minister. He commanded the army of Brazil against Paraguay in 1866-9, and from 25 June 1875 to 5 Jan. 1878 was a third time premier.

Limburg, lim'boorg, or Limbourg, läin-boor, (1) a province in the northeast of Belgium, separated from the Netherlands province of Limburg by the Maas or Meuse; area, 931 square miles; pop. (1900) 240,796. It is flat throughout, and a considerable part of it, particularly toward the north, belongs to the Campine (see BELGIUM), and is desolate in the extreme. Hasselt is the capital, (2) a province in the Netherlands, partly bounded by Rhenish Prussia and Belgium; area, 850 square miles; pop. (1901) 292,072. It is partly flat, partly undulating, rich and fertile along the Maas, but in the north and west cold and sterile, large portions being covered with heath and marsh. Besides Maastricht, its chief towns are Roermond, Venlo, and Weert. There was formerly a county and duchy of Limburg. See BELGIUM; NETHERLANDS.

Lim'bus, a name given in Roman Catholic theology to the place where the patriarchs remained until the advent of Christ, who, before his resurrection, appeared to them, and opened the doors of heaven for them.

Lime, also known as caustic lime, quicklime or calcium oxide (CaO) is snow white in color and strongly alkaline, being one of the strongest bases. In contact with water for which it has great affinity it increases in bulk, evolves much heat and changes to the hydrate (CaH_2O_2). Unless kept in a dry place it will absorb moisture and carbonic acid gas from the air and change to the carbonate (CaCO_3) (see CALCIUM). Lime except for certain impurities is entirely soluble in water, the principal insoluble impurities being silica, alumina and iron oxide. It is never found native. For ordinary commercial uses lime is obtained by heating limestone, shells or other material composed of calcium carbonate to a temperature high enough to drive off the carbonic acid gas. As the materials used vary in purity, so is there a corresponding difference in the purity of the lime produced. Owing to its property of hardening, by change to calcium carbonate, and its comparative cheapness, lime is the most important of building materials. For commercial purposes the many varieties of lime are grouped into, (1) common or fat limes containing less than 10 per cent. of impurities, (2) poor or meagre limes containing 10 to 25 per

cent. of impurities, (3) hydraulic limes containing 15 to 40 per cent. of impurities and (4) hydraulic cements which may contain as high as 70 per cent. of impurities.

Common or fat limes in slaking evolve much heat and increase in bulk from two and a half to three times; except for some impurities they are entirely soluble in water. In hardening they shrink, and hence in making mortar require the addition of a large amount of sand. As fat limes are cheap and abundant and can take a large proportion of sand in making mortar, they are generally used for masonry. The poor or meagre limes are seldom used in this country. The hydraulic limes, so called from their property of hardening under water, though valuable for certain purposes, are also seldom used in the United States for masonry. They slake more slowly than ordinary limes with little rise of temperature and little increase in volume. Hydraulic cements (see CEMENT) do not slake and do not require the addition of sand to form mortar. They also set or harden much more quickly than ordinary limes, as the formation of calcium carbonate is a slow process that may under certain conditions take years, while in some quick-setting cements the formation of the calcium silicates and aluminates to which setting is due may take place in a few hours.

Limestone, marble and shells are burnt to lime by exposure to a temperature of 850 to 900° C. in a current of air. The harder the limestone the longer the time required for burning, but the better the product. Impurities in the limestone may or may not be injurious, depending on the quality of lime desired. Moisture in the limestone, or added to the charge, as by a steam jet, helps carry off the carbonic acid and hastens burning. Lime burning may be done in heaps or kilns. Heap burning in which pieces of limestone are piled on a grate of wood, then covered with fines or clay and fired, is now little used. Of kilns there are various types, intermittent and continuous firing. Of intermittent kilns the old "dug out" kilns built of ordinary brick on masonry into the side of a hill require about 72 hours for each firing. Heat is supplied by a coal or wood fire at the bottom. For continuous firing vertical kilns 20 to 25 feet high with draw openings, preferably below the fire line, are used, the lime being drawn every six hours. To supply moisture, water is kept in an iron pan in the ash-pit. In the kilns most commonly used there is no grate, but the fuel, preferably charcoal or anthracite, is charged with the limestone. The lime is not as pure as from furnaces with a bottom grate, but the consumption of fuel per pound of lime made is less. In such kilns burning is started by partly filling the kiln with limestone, putting in a thick layer of kindling wood and coal, starting the fire, and then adding alternate layers of coal and limestone. The type of continuous kiln in most favor is vertical, about 25 feet high, bottle-shaped and made of boiler iron lined with fire brick. Such a kiln may use petroleum for fuel, the oil being injected through openings in the wall just above the widest part of the furnace. Vertical kilns fired with gas have not proved successful. The type of kiln that requires the least fuel for amount of lime produced is the horizontal circular Hotman kiln, also used for making brick, drain tile, etc. The fuel is fine coal or even coal dust, and is put in through openings in the top. The lime pro-

LIME — LIMESTONE

duced is lighter than that from vertical kilns, stakes more easily and hence cannot be stored as well.

Most of the lime made is used for building purposes, but lime is also used for making glass and artificial stone, as an agent in many chemical processes, as whitewash, and was until recently largely used in sugar-making to separate sugar from molasses. No statistics of the amount of lime annually made in the United States have been compiled, but the value of the 1901 output was over \$8,400,000. See LIMESTONE.

S. SANFORD,

Assoc. Editor 'Eng. and Min. Journal.'

Lime, a shrub or small tree (*Citrus medica*, var. *acida*), a variety of the citron (q.v.) resembling the lemon in habit but rather more prickly and spreading; its fruits, also, are more nearly spherical, more acid and rather bitterer than commercial varieties of lemon. It is a native of southeastern Asia, whence it has spread to other warm countries where its juice is highly valued for making cooling drinks. In Florida and the West Indies, which supply the American market, large thickets of wild limes are to be found and these add to the crops from the cultivated groves. In California the lime is little cultivated because the cheapness of Mexican fruit prevents the realization of a profit from orchards. The lime is one of the most important sources of citric acid (q.v.). The trees are propagated, cultivated and trained much like lemon trees, but are planted closer together. They will stand poorer, stonier soil and nearer proximity to the ocean than other citrus fruits. The name is given in the Orient to various sour-fruited trees related to the true lime; in Europe and occasionally in the United States to the lindens (q.v.); and locally in the Southern States to the sour tupelo (q.v.), whose tart fruit is eaten.

Lime Light. See CALCIUM LIGHT.

Limerick, lim'ē-rīk, Ireland, a city and civic county, capital of Limerick county, at the interior extremity of the estuary of the Shannon, 106 miles by rail southwest of Dublin. It consists of three portions connected by five bridges, English Town on King's Island, and Irish Town and Newtown Pery on either side of the river. Limerick is of very ancient foundation, being mentioned by Ptolemy as Regia. The principal buildings are the Episcopal and Roman Catholic cathedrals, custom-house, chamber of commerce, town-hall, exchange, assembly-house and linen-hall. The manufactures include the curing of bacon, the preparation of butterine, and the making of army clothing. There are, besides, distilleries, breweries, tanneries, corn-mills, a patent slip for vessels of 500 tons, and a large graving-dock. Limerick is the leading port on the west coast for the shipment of raw produce. The

harbor, naturally a fine one, has been improved at a considerable outlay. Pop. (1901) 45,806.

Limestone, a common and widely distributed rock, consisting essentially of carbonate of lime and varying greatly in composition, color and texture. Most limestones are of organic origin and represent the calcareous remains of sea animals, such as corals, foraminifera and mollusks. These remains may be reduced to a fine ooze by the action of the waves and in other ways, and the rock resulting from the consolidation of this ooze may show no trace of organic origin. Some limestones have been formed by the precipitation of calcium carbonate from sea water through evaporation in confined estuaries. Other limestones (travertine, calcareous tufa) have been formed by the deposition of calcium carbonate from springs, while still others represent calcareous deposits in fresh-water lakes. The varieties of limestone are almost endless, including the crystalline limestones or marbles. Thus starting with nearly pure calcium carbonate, the calcium may be replaced gradually by magnesium till finally we have dolomite, the double carbonate of calcium and magnesium. Pure dolomite contains 21.72 per cent of magnesia, but limestones containing over 5 per cent are said to be dolomitic. Again the lime may be replaced by silica, with a gradual transition from limestone through cherty limestone to pure cherts; or again iron oxide may replace lime with a resulting transition from limestone to merchantable iron ore. Besides these chemical transitions siliceous or argillaceous sediments may be laid down with the calcareous material, and in the resulting rocks we may trace gradual changes from limestone through limy sandstones to pure sandstone and from limestone through marls or calcareous shales to ordinary shales. Bituminous matter may make limestone black or give rise to asphaltic varieties. Besides all these varieties of composition, limestones are often classified according to their texture, as earthy limestone, oölitic limestone with a concretionary texture, like the roe of fish, etc. Under rock stresses, with possible rise in temperature, limestones become crystalline and change to marbles. Chalk is a soft and powdery textured limestone. Limestones are also classified according to the uses to which they are put, and thus we have cement rock or hydraulic limestone used for making cement, lithographic limestone, statuary marble, etc.

The various limestones and marbles are widely used for building purposes, and a great amount of limestone is annually burnt to lime or to cement, though no statistics of the amount thus used are available (see CEMENT, LIME). Limestone is also used as a flux in smelting iron and other ores, the total amount thus used in the United States in 1902 amounting to fully 9,000,000 tons. Of the limestones used for build-

LIMICOLÆ—LIMPET

ing purposes particular mention may be made of the buff or blue oölitic Bedford limestone of Indiana and of the marbles of Vermont, Georgia and Tennessee. Marble or limestone is also used as a source of carbonic acid gas for aerated waters. The total value of the limestone and marble produced in the United States in 1901 was fully \$31,000,000. See CALC-TUFA; CALCITE; CHALK; CORAL; DOLOMITE; see also MARBLE.

S. SANFORD,

Assoc. Editor 'Eng. and Min. Journal.'

Limicolæ, li-mik'ō-lē, a group of birds, within the order *Charadriiformes*, containing the plovers, sandpipers, snipes, sheathbills, coursers, seed-snipes, stone-curlews, jacanas (q.v.) and their immediate allies, most of which are known to gunners as "shore birds" or "beach birds", because they haunt the shore of the sea or of inland bodies of water. They are mostly small, with slender bills of varying length, grooved for the nostrils, and in some families flexible at the tip, where nerves come close to the surface and enable the bird to feel about in the mud for its food. The legs are rather long, and the toes are ordinarily quite free, as these birds run about, and do not wade or swim as a rule; some, indeed, rarely approach the water, but dwell upon dry plains. The wings are strong and the powers of flight considerable; the most extensive migrations known are performed by some of the limicoline birds. All make their nests on the ground, and many breed only in the far north; the young run about as soon as freed from the shell. Light and pleasing, but not conspicuous colors prevail, but some species display great beauty. Nearly all are edible and are the objects of skilful sport by the aid of dogs, decoys and other devices to overcome their wit and wariness. Consult Evans, 'Birds' (Vol. I., Cambridge Natural History, 1900); Steineger, 'Birds' (Vol. IV., Standard Natural History, 1885); Elliot, 'North American Shore Birds' (1805); Baird, Brewer and Ridgway, 'North American Water Birds' (1884); Sclater & Hudson, 'Argentine Ornithology' (1888); and general works on ornithology and shooting.

Limited Liability, in modern statute law, a principle whereby the persons liable are bound under certain clearly defined conditions. The phrase is chiefly used in connection with stock companies, meaning that the stockholders shall not be called upon, under any circumstances, to contribute more than the par value of the shares of stock for which they have subscribed. If the debts of such a company, when wound up, amount to more than the resources of the company can meet, the creditors must bear the loss. In the United States shareholders in national and other banks, insurance companies, etc., are held to a specific and strict liability; in the case of the national banks, it is for twice the amount subscribed. In England the shareholders of a limited company from whose name the word "limited" is omitted must pay its debts in full. The United States Congress has adopted the rule followed by the British Parliament, and prevailing in European countries generally, with respect to the maritime law (q.v.) whereby a ship-owner, by surrender of the ship and the freight, may absolve himself from liability for negligence on the part of master or crew. Under the amended United States Revised Stat-

utes the principle of limited liability is clearly maintained and defined as applicable in this country; wherefrom it appears that "the owner of any vessel, whether steamer or canal-boat, employed whether in seagoing or inland navigation, whether he be an American citizen or a foreigner, may obtain a limitation to the value of his interest in the vessel and her pending freight, of his liability not only for the results of a single disaster, but for the results of a disastrous voyage, including all debts due on account of the vessel save seamen's wages".

Limne'a, the central genus of the pulmonate family *Limneidae*, containing the typical fresh-water snails. See POND-SNAILS.

Limoges, lē-mōzh, France, an episcopal city, capital of the department of Haute-Vienne, situated on a hill sloping to the Vienne, here crossed by three bridges, 88 miles west of Clermont. The fortified walls which surrounded the town have been replaced by fine shady boulevards. The principal edifices are the cathedral, commenced in 1273, presenting both Romanesque and Gothic features; the Gothic church of St. Michel des Lions; the church of St. Pierre du Queyroi; a modern town-hall, palace of justice, bishop's palace, public library, and several hospitals. The principal industry is the manufacture of porcelain; there are also wool and cotton spinning mills, cloth factories, foundries, paper-mills, and extensive shoe and clog making establishments. Limoges has a considerable trade in cereals, wine and spirits, wood, and cattle. It is the seat of courts of first resort and commerce; of a consulting chamber of commerce, lyceum, preparatory school of medicine, normal schools for male and female teachers, etc. Limoges was originally the capital of the Gallic tribe, the Lemovices, and an important city to the Roman "Augustoritum Lemovicum." Pop. (1901) 83,569.

Limon, lē-mōn', or **Puerto Limon**, poō-är-tō lē-mōn, Costa Rica, Central America, a port on the northeast coast, 72 miles (103 by rail) east of San José, the capital. A railway connects with Cartago, San José, Alaguila and Puenta Arenas. The port has been greatly improved by modern docks and iron piers, and a growing export trade is carried on especially in coffee, also in bananas, rubber, mahogany, dye-wood, etc. The town has ice factories, a brewery, a fine water supply, and a modern sewerage system. Pop. (1903) 4,000.

Li'monite (Greek λειμών, a meadow), an ore of iron (q.v.), varieties of which are bog iron-ore and yellow ochre. It is a hydrated oxide of iron ($2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$), of a brownish color, occurring in mammillated or botryoidal masses, which when broken across show a fibrous radiating structure, and also in compact and earthy masses. It is opaque, rather brittle, moderately hard, and has specific gravity 3.6 to 4. It dissolves in warm aqua regia; when heated it loses water and becomes magnetic. It is a very important ore of iron, and is found abundantly in the United States, especially in Virginia and Alabama, and in other parts of America; also on the continent of Europe, and in some parts of Great Britain. In 1901 the United States produced over 3,000,000 long tons of this ore.

Limp'pet, a gastropod mollusk, with a low conical, non-spiral shell; properly a representa-

LIMPKIN—LINCOLN

tive of the families *Patellidae* and *Acmaeidae*. The former has no *ctenidia* or true gills, but breathe by means of a ring of special branchial filaments between the mantle and the foot; in the latter the left *ctenidium* functions as a gill and there is no accessory ring. By means of a muscular, sucker-like foot, the limpets adhere so firmly to rocks near low-water mark that they defy the beating of the heaviest surf and are difficult to detach without injury. At high-tide they move about in search of the algae on which they feed, but are said to return to exactly the same place and position, the muscle in time wearing a smooth spot or "form" on the rock, and the shell becoming adapted to its irregularities. A widely distributed circum-polar species (*Acmaea testudinalis*) is common on the New England coast, and may be recognized by its low, conical, smooth shell with the eccentric apex slightly turned forward. In Europe limpets are utilized as food and in this country for bait. The key-hole limpets belong to the family *Fissurellidae*, in which the shell is usually perforated like a key-hole at the apex to permit the protrusion of a process of the mantle. Numerous species occur in the littoral zone of warm seas. The *Haliotidae*, ear-limpets or abalones (q.v.) are closely related. The cup-and-saucer limpets and slipper-limpets (*Calyptotræide*) have flat shells usually provided with an internal lip or shelf. Several species of *Crepidula*, having interesting commensalistic habits, are abundant on our coasts, and are known to fishermen as "half-decks." Finally the fresh-water limpets (*Ancylus* and *Gundlachia*) belong to the pulmonate family *Limnaeidae*. Numerous species of these true air-breathing limpets are found abundantly on stones and plants in the fresh-water streams and ponds of the United States. They feed on *confervæ*. Limpets, especially *Acmaea* and *Patella*, are of very ancient race, having existed almost unchanged since the Silurian Age.

Limp'kin, a crane-like bird of the swamps of tropical America, known and superstitiously half-feared by the more ignorant natives of Central America and the West Indies, on account of its sombre plumage and wailing cry. Two species exist, *Aramus scolopaceus* and *A. pictus*.

Limpopo, lim-pō'pō, or **Crocodile River**, South Africa, a river which rises to the south of Pretoria in the Witwatersrand, flows northwest through the Transvaal, then northeast, forming for a considerable distance the northern boundary of the Transvaal, then southeast into the Indian Ocean north of Delagoa Bay; length about 1,100 miles. Its largest tributary is the Olifants, which flows through the eastern part of the Transvaal and joins it in Portuguese territory.

Lim'ulus. See **HORSE-FOOT CRAB**.

Linares, José María, hö-sā' mä-rē'ä lē-nä'-rēs, Bolivian statesman: b. Potosí 10 July 1810; d. Valparaiso, Chile, 1861. He was admitted to the bar, was appointed one of the commissioners to prepare a legal code for Bolivia, in 1839 became minister of the interior, later minister to Spain, and in 1848 president of the senate. In 1857 he was chosen president. His administration was admirably progressive, but his policy was opposed, and he was deposed by revolutionists in January 1861.

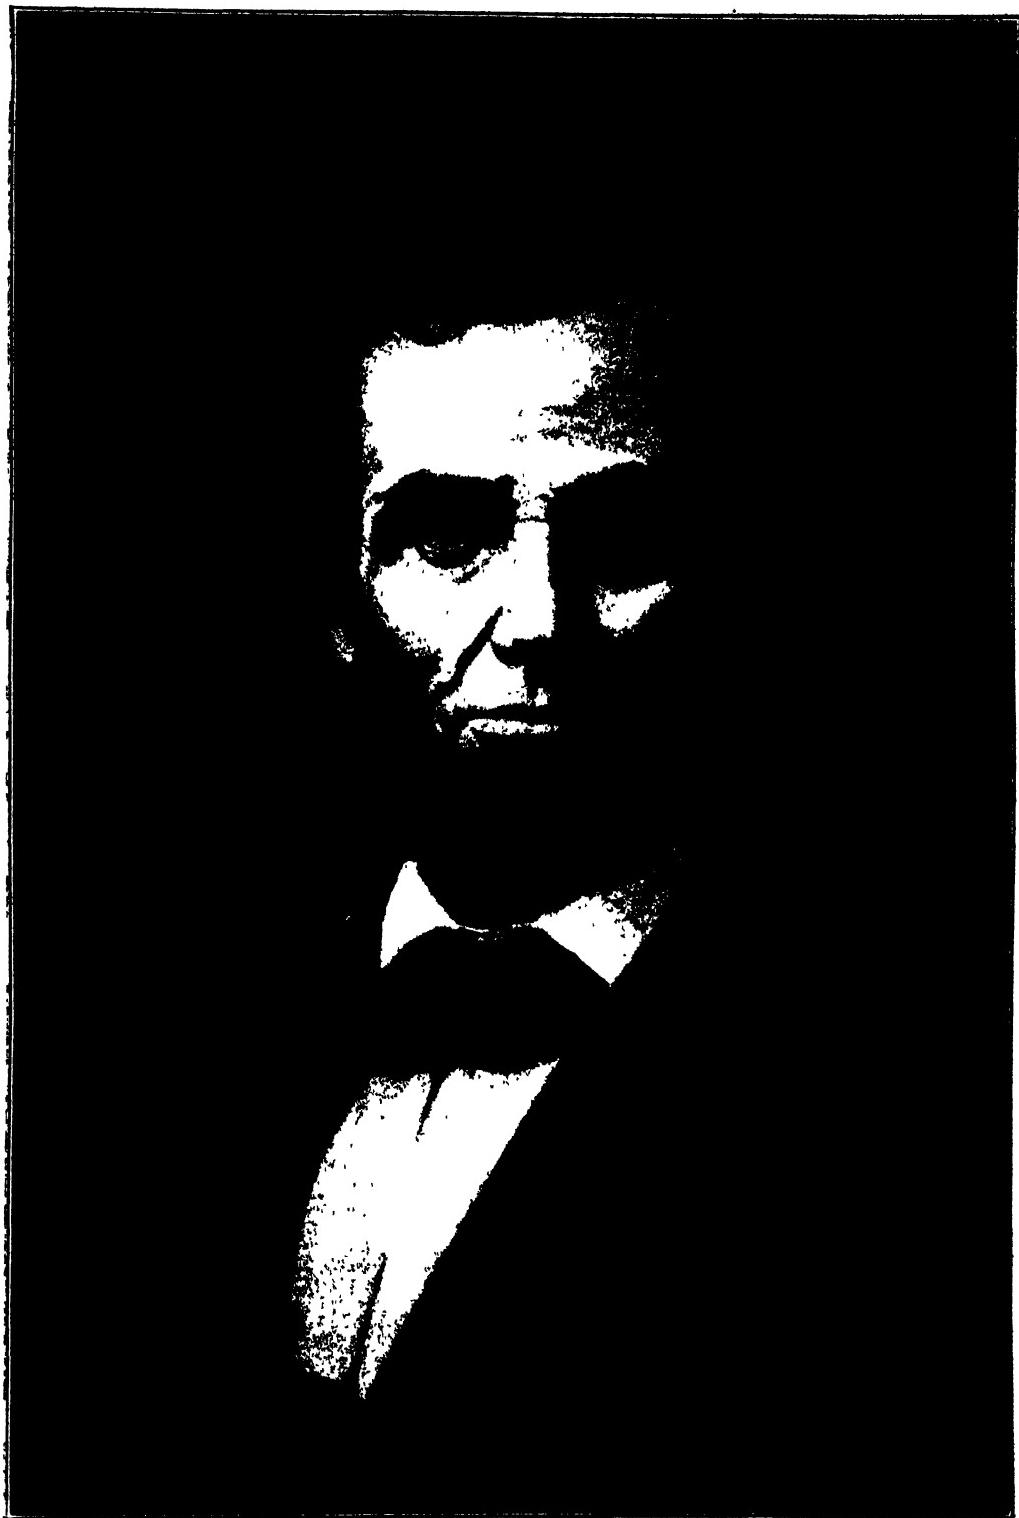

Linares, Chile, (1) a southern province bounded north, south, and west by the provinces of Talca, Nuble, and Maule, and on the east by the Andes; area, 3,589 square miles; pop. (1895) 101,858; (2) a town, the capital of the above province, 10 miles southeast of Talca. Pop. (1895) 7,331.

Lincoln, Abraham, 16th President of the United States: b. Hardin County, Ky., 12 Feb. 1809; d. Washington, D. C., 15 April 1865. His ancestors were English Quakers, who settled in America in the 17th century. His grandfather, Abraham Lincoln, a man of property, removed from Virginia to Kentucky about 1780 with three sons. Thomas, the youngest son, learned the carpenter's trade, and married (12 June 1806) Nancy Hanks, a handsome young woman of lowly condition but possessing qualities of intellect and character above the average. From this union came three children: the oldest a daughter; the second, named Abraham; the third, a son who died in infancy. Abraham's parents were plain people, and the log-cabin they lived in was a true home. The father could not read or write (except to scrawl his signature); he was always poor, and is described as shiftless. The mother could read but not write. A woman of piety and excellent judgment, she left an indelible impress on her son. From her he inherited the serious temperament, brightened by the spirit of playfulness that was so prominent a trait of the man throughout his troubled career. She died in 1818, and the boy of 9 deeply mourned her loss. In later years he said: "All that I am, and all that I hope to be, I owe to my angel mother."

In 1816 Thomas Lincoln sold his Kentucky farm and found a new home in a sparsely-settled district of Spencer County, Indiana. In his boyhood Abraham learned the use of firearms, and helped his father cut down trees. He got, all told, a year's schooling. His teachers were men who never went "beyond readin', writin', and cipherin' to the rule of three." The boy eagerly devoured the few books that fell into his hands: the Bible, *Aesop's Fables*, '*Pilgrim's Progress*', '*Robinson Crusoe*', and the lives of Washington and Henry Clay. After he grew up he kept on reading and studying, and gained what must be considered a fair education, including Euclid and the rudiments of surveying. In childhood he had a passion for re-stating, in clear language, the confused and not over-intelligible ideas of others. In this way he acquired his unusual power of "putting things." When a youth he practised speaking in public on temperance and political subjects.

At the age of 20, Abe Lincoln, as he was called, had grown to extraordinary stature, nearly 6 feet 4 inches, and his great muscular strength was the talk of the neighborhood. He had developed his native vein of humor, which afterward made him famous. From the life of a woodman he turned to flatboating, making a voyage down the Mississippi to New Orleans and back with one companion.

In 1830 Thomas Lincoln, who had married an estimable widow, Sarah Bush Johnston, moved to Sangamon County, Illinois. From this home he departed in a short time to Coles County, where he died in 1851. Meanwhile his son had found employment as a farm hand and

ABRAHAM LINCOLN,
SIXTEENTH PRESIDENT OF THE UNITED STATES.

LINCOLN

railsplitter. With his rifle he supplied the family with game in the hard winter of 1830-1. In the spring of 1831 he made another flatboat trip down the Mississippi. After his return he clerked in a grocery at New Salem, and became known among his acquaintances as "Honest Abe." In 1832 he served in the Black Hawk war, part of the time as captain of a volunteer company, but saw no fighting. Later he became a storekeeper, postmaster, and at intervals worked at surveying. He was a Whig member of the Illinois legislature eight years (1834-42), and as a legislator he made a creditable record, and through his influence the State capital was removed from Vandalia to Springfield in 1839.

Having studied law, Lincoln was admitted to the bar in 1836, and the next year began his law practice in Springfield, as partner of John T. Stuart. Among his associates in the Illinois capital were men who afterward achieved eminence in law and politics. It is enough to say that Lincoln held his own in legal combats with the best of them. In these years he met the man destined to be his political rival, Stephen A. Douglas. In 1841 he formed a new partnership with Stephen T. Logan, and from 1843 to his death was senior partner with William H. Herndon, whom he generally called Billy.

While Lincoln earned and deserved the reputation of being an able lawyer, he was never a learned jurist. His leisure was spent in general reading, history, and political economy. English grammar he had mastered by himself, and he acquired skill in composition by writing out an epitome of each book he read. Thus the young lawyer laboriously schooled himself in thinking and in the art of expressing himself clearly and correctly. In the court-room it was characteristic of him to waste no time on unessentials, but to spend his strength on the one point that was really the heart of the case. Sometimes his pleas were surprisingly short. A good illustration of his terse manner of speaking is his address to the jury in the suit against a man known as "King" Hart for seizing a piece of land from the plaintiff, Lincoln's client. The trial was held at Metamora, Woodford County. During the trial he had little to say and the case was seemingly lost, but he gained a prompt verdict by this brief speech: "We don't believe in kings in this country. We refuted that doctrine almost 100 years ago, but we have a doctrine in this country that we do believe in. It is the Monroe Doctrine. When the kings of Europe attempt to seize land in this hemisphere we apply the Monroe Doctrine to them and they experience a change of heart. Why should we not apply the same doctrine to American kings? This little king is attempting to secure possession of land to which he has no claim, and you, gentlemen of the jury, stand in the same position as the government of the United States; you must protect a weak vassal by applying the Monroe Doctrine to this American king."

Lincoln's law practice grew and he prospered, although many of his clients were poor and fees were sometimes nothing. Success had come, but the death of his sweetheart clouded his life and deepened his melancholy. He married (4 Nov. 1842) Mary Todd, a woman belonging to an influential family of Lexington, Ky. Though a devoted wife, she was not his

heart's choice. They had four sons, of whom only the eldest, Robert Todd, is living.

There is truth in the statement that Lincoln was too much of a politician to be a great lawyer. He took more than a passing interest in politics and he was quick to improve opportunities for political advancement. In the election of 1844 he "stumped" the State as the champion of the Whig party, making many speeches on the tariff question, which he had thoroughly studied. He spoke familiarly, mingling argument with anecdote and attempting no flights of oratory. His homely illustrations and striking utterances left a deep impression on his audiences. To enter Congress had long been his ambition, and in 1846 he was elected as representative from the central district of Illinois. He was the only Whig from his State, his six colleagues being Democrats. During his term (1847-9) he held with his party in favoring a protective tariff and in making appropriations for public improvements. Although opposed on principle to the Mexican War, he invariably voted for granting supplies needed by soldiers in the field. In 1858 he said (in debate with Douglas): "Whenever the Democratic party tried to get me to vote that the war had been righteously begun by the President, I would not do it." Already he had pronounced views on the question of slavery. When a member introduced a bill to abolish the slave-trade in the District of Columbia, Lincoln proposed an amendment for the abolition of slavery in the District. He always supported the Wilmot Proviso, voting for it about forty times. He was not a candidate for re-election, but applied for the office of commissioner of lands. This position he failed to get. Instead he was offered the governorship of Oregon, which he declined.

Returning to Springfield, Lincoln resumed the practice of law. Meanwhile he closely watched the signs of the times, foreseeing trouble with the slaveholders because of their manifest intention to encroach upon the soil of the Western Territories. He was deeply stirred by the repeal of the Missouri Compromise in 1854 and entered actively into the canvass of that year. In this memorable campaign he was pitted against Stephen A. Douglas, the "Little Giant." The first debate between the two men was at the State Fair (in October), before a vast multitude. Lincoln's speech on this occasion was regarded the ablest effort of this campaign. Its keynote is in the following passage: "My distinguished friend says it is an insult to the emigrants to Kansas and Nebraska to suppose they are not able to govern themselves. We must not slur over an argument of this kind because it happens to tickle the ear. It must be met and answered. I admit that the emigrant to Kansas and Nebraska is competent to govern himself, but I deny his right to govern any other person without that person's consent." The second meeting of the two champions was in Peoria, and after Lincoln had finished, Douglas (as a hearer remarked) "hadn't much to say." Thereafter the "Little Giant" kept out of the way of his antagonist. Through Lincoln's influence Lyman Trumbull, the candidate of the anti-Nebraska (afterward Republican) party, was elected United States Senator. The same year Lincoln declined the nomination for governor.

LINCOLN

In the first Republican National Convention, held at Philadelphia in 1856, Lincoln received 110 votes for the vice-presidency on the ticket with John C. Fremont. When the choice of the convention fell upon Fremont and Dayton as the standard-bearers of the new party, Lincoln entered earnestly into the campaign. His name headed the electoral ticket of Illinois. In those years Lincoln had a great reputation as a campaign speaker, and was a tower of strength to his party. The common people recognized him as a diamond in the rough and he was admired and trusted even by his enemies. His speeches were masterly and held his audiences spell-bound. No other orator of the period could equal him in the rare combination of wit, argument, and dramatic power. A contemporary who saw and heard him gave this word-portrait of the man: "At rest, his features, though those of a man of mark, are not such as belong to a handsome man. . . . His head sits well on his shoulders, but beyond that it defies description. . . . It is very large and, phrenologically, well proportioned, betokening power in all its developments. A slightly Roman nose, a wide-cut mouth, and a dark complexion, with the appearance of having been weather-beaten, complete the description."

The Lincoln-Douglas joint debate of 1858 has become historic. It was more than a contest between two rival candidates for a seat in the United States Senate. The discussion was one in which the whole nation was deeply concerned. It was a critical moment in the long-drawn struggle between North and South over slavery, and public feeling ran high. Lincoln was the strongest man in the Republican party, and Douglas was the recognized leader of the Democratic party. Lincoln threw down the gauntlet in a letter asking Douglas to divide time with him and address the same audiences in the coming canvass. Douglas was reluctant to accept the challenge, but consented to make appointments to debate with Lincoln in the several congressional districts of Illinois. "I agree to your suggestion," he wrote (30 July 1858), "that we shall alternately open and close the discussion. I will speak at Ottawa one hour, you can reply, occupying an hour and a half, and I will then follow for half an hour. At Freeport, you shall open the discussion and speak one hour; I will follow for an hour and a half, and you can then reply for half an hour. We will alternate in like manner in each successive place." By this arrangement Douglas had four opening and closing speeches to Lincoln's three, a distinct advantage. They appeared together before tremendous assemblages of people, at Ottawa (21 Aug.), Freeport (27 Aug.), Jonesboro (15 Sept.), Charleston (18 Sept.), Galesburg (7 Oct.), Quincy (13 Oct.), and Alton (15 Oct.). Throughout this celebrated word-duel Lincoln kept his temper and treated his opponent with courtesy and fairness, indulging in no offensive personalities. Douglas was acknowledged to be the ablest debater in Congress, and he never spoke with greater eloquence. He took with the crowd and won much applause, while Lincoln left the deeper impression. He set his hearers to thinking on and discussing the absorbing question of the day. The great difference between him and Douglas was that he took higher moral ground, in holding slavery to be a wrong. He appealed to

reason and conscience. The immediate result of these debates was Douglas' election as senator. The far-sighted Lincoln looked ahead to the contest for the presidency, assured that Douglas could not win in 1860.

From this time Lincoln's reputation was national, and he received invitations to speak in other States. In May 1859, the Republican party of Illinois declared Lincoln to be its choice for the presidential nomination in 1860. In September he addressed audiences in Columbus and Cincinnati. In December he spoke at several prominent points in Kansas, making a profound impression. On 27 Feb. 1860 he visited New York and delivered his famous Cooper Union oration, followed by speeches in New England. All his utterances had a bearing on the matter of the extension of slavery. He stood forth as the defender of the right of freedom. The development of events made him the nominee of the party of freedom, when the Republican National Convention met in Chicago (16 May 1860). Hannibal Hamlin, of Maine, was nominated for vice-president. The Democrats were divided, the candidate of the Northern wing of the party being S. A. Douglas, while the pro-slavery section nominated J. C. Breckinridge. Another candidate, John Bell, was put forward by old-time Whigs and others. A combination of circumstances gave Lincoln the victory at the polls. The electoral vote stood 180 for Lincoln, 72 for Breckinridge, 39 for Bell, and 12 for Douglas.

During the four remaining months of Buchanan's administration the storm of secession gathered in the South, and the movement was promoted by the treachery of John B. Floyd, then secretary of war. A number of United States arsenals and forts in the South, with many stands of arms, were seized by State troops. The Confederate Congress, representing South Carolina, Georgia, Alabama, Mississippi, Louisiana, and Florida, met (4 Feb. 1861) at Montgomery, Ala., and chose Jefferson Davis president and Alexander H. Stephens vice-president of the seceded States. On 18 Feb. Davis was inaugurated president. Lincoln watched the course of events in silence until the eve of his departure (11 Feb.) for Washington, when he took leave of his friends and neighbors in an address that was in parts deeply religious. "I go to assume," he said, "a task more difficult than that which has devolved upon any other man since the days of Washington. He never would have succeeded except for the aid of divine Providence, upon which he at all times relied. I feel that I cannot succeed without the same divine blessing which sustained him; and on the same Almighty Being I place reliance for support." After visiting Cleveland, Buffalo, New York, and other cities, he passed through Baltimore in disguise, because of a plot to take his life. He reached Washington (23 February) and was inaugurated 4 March. Although an untried man, unknown to the majority of the people outside of his own State, the new President made a favorable impression and inspired confidence in his ability to cope with a serious situation. According to his position, repeatedly stated, the nation could not permanently remain half slave and half free; he expected that sooner or later slavery as an institution would disappear. How and when, he left to be settled by the logic of events. He argued that "no

STATUE OF ABRAHAM LINCOLN, BY SAINT-GAUDENS.

IN LINCOLN PARK, CHICAGO.

LINCOLN

State upon its own motion can lawfully get out of the Union." The members of his cabinet were: W. H. Seward, secretary of state; S. P. Chase, secretary of the treasury; Simon Cameron, secretary of war; Gideon Welles, secretary of the navy; G. B. Smith, secretary of the interior; Edward Bates, attorney-general; Montgomery Blair, postmaster-general. In January 1862 Edwin M. Stanton succeeded Cameron, and there were other changes in the cabinet later. Seward, Welles, and Stanton were continued in office in his second administration.

The story of Lincoln's life the next four years is involved in the history of the Civil War. Although the South was busy preparing for war, the people of the North were slow to act, hoping in vain for peace. The lull before the storm lasted several weeks until the firing on Fort Sumter (12 April 1861). War had been begun by the slaveholders of the seceding States, and President Lincoln issued a call (15 April) for 75,000 troops. On 19 April he proclaimed the blockade of all ports of the Confederate States. Volunteers for three years were asked for, and recruits for the regular army and navy. Meanwhile Texas, Virginia, Arkansas, North Carolina, and Tennessee had seceded. Congress met in extra session (4 July). In a memorable message Lincoln referred to the attack on Fort Sumter, saying that "no choice was left but to call out the war-power of the government, and so to resist the force employed for its destruction by force for its preservation." Congress passed measures for the energetic prosecution of the war, and the North was encouraged by several successes in the latter part of the year.

It was, however, a war to save the Union, not to destroy slavery. That was Lincoln's object in 1861. Fugitive slaves coming into the camp of General B. F. Butler were set to work for the Federal government, and a record was kept of them with the view of compensating loyal owners. The Confiscation Act (passed 6 August) affected only the slaves of rebel masters who "required or permitted" them to aid the rebellion. The President disapproved and countermanded General Fremont's remarkable order, freeing the slaves of active rebels. Time proved the wisdom of his policy of going slow in the matter of the emancipation of the slaves. In the Trent affair popular feeling was at first against Lincoln for surrendering Mason and Slidell, the Confederate envoys to Great Britain and France, but his common-sense course, though humiliating to national pride, was approved by the sober second thought of the people.

General Winfield Scott retired (1 Nov. 1861) and was succeeded as commander-in-chief by General George B. McClellan, who had organized and drilled an effective army but was slow to make an advance against the enemy. President and people grew impatient at his long delay and (11 March 1862) he was relieved from chief command, though retaining command of the Department of the Potomac. In the meantime General U. S. Grant, in co-operation with Commodore Foote, captured Forts Henry and Donelson, and the little Monitor had worsted the Merrimac. In the spring and summer the Federal armies were successful at Shiloh, New Orleans, Malvern Hill, and Antietam. The sec-

ond battle of Bull Run and the battle of Fredericksburg were lost. On the whole, progress had been made, notwithstanding many blunders on the part of Northern generals. The President, not being a military expert, had also made mistakes of judgment in directing the movements of troops. The end of the struggle seemed far off.

On 1 Jan. 1863 the Emancipation Proclamation, freeing the slaves, went into effect. Congress had previously passed a bill abolishing slavery in the District of Columbia, and slavery had been prohibited in the Territories. Volunteers of African descent were enlisted, and on 22 Sept. 1862 the President's preliminary proclamation announced that in territory still in rebellion (1 Jan. 1863) slaves would be declared forever free. The act of emancipation was a military necessity. In his message to Congress (1 Dec. 1862) Lincoln recommended that loyal owners be compensated. Before the Thirty-seventh Congress adjourned (4 March 1863) it empowered the President to suspend the writ of *habeas corpus* and authorized the loan of \$300,000,000 for carrying on the War in 1863. The number of Union soldiers on duty was about 700,000, and a call for 300,000 more was issued (17 October). From time to time more treasure and men were forthcoming, as the country gradually realized the magnitude of the conflict. The campaigns of 1863 resulted in great gains to the North, the most notable victories being at Gettysburg (1-3 July), Vicksburg (4 July), and Chattanooga (25 November). The battle of Gettysburg has been called the turning-point of the war. A portion of this field was set apart (19 November) for a national cemetery, and at the dedication Lincoln delivered an address so compact and felicitous in thought and statement that it has become a classic. His thanksgiving proclamation of this year was marked by lofty sentiment and rare beauty of language.

Henceforth the South waged a losing fight. Grant took chief command (10 March 1864) as lieutenant-general and won the hard-fought battles of the Wilderness (5-6 May), Spottsylvania (10 May), and Cold Harbor (3 June). Sherman took Atlanta (2 September), and Savannah (21 December). Decisive blows were struck by Farragut, Sheridan, Thomas, and other Federal commanders. At the National Republican Convention, which met at Chicago in June 1864, Lincoln was renominated on the first ballot; Andrew Johnson, of Tennessee, was nominated vice-president. The overwhelming majority for Lincoln on election day showed conclusively that the people were with him. His second inaugural (4 March 1865) justly ranks as the greatest of his public utterances. The war was all but ended, there being one more battle, Five Forks (1 April), before Lee's surrender at Appomattox (9 April). The rejoicing of the nation was suddenly turned to mourning when the President was shot in Ford's Theatre, Washington, on the evening of 14 April, by John Wilkes Booth. He lingered unconscious and died the next morning. His remains, after lying in state in the Capitol, were borne to Springfield and there buried (4 May). His tragic end as well as his public services had gained him a place in the hearts of his countrymen not second to that of Washington, and in the estimation of

LINCOLN

many he was and is regarded as the greatest of Americans.

Consult: Lincoln's complete works, edited by Nicolay and Hay (2 vols. 1894); lives by O. J. Victor (1864), L. P. Brockett (1865), H. J. Raymond (1865), J. G. Holland (1866), W. O. Stoddard (1884), I. N. Arnold (1885), Nicolay and Hay (1890), Carl Schurz (1891), J. T. Morse (1893), N. Brooks (1894), N. Haggard (1899), I. M. Tarbell (1900), W. E. Curtis (1903); also reminiscences by A. T. Rice (1886), F. F. Browne (1886), H. C. Whitney (1892), W. H. Herndon (1892), and W. H. Lamon (1895).

EUGENE PARSONS,
Author and Editor.

Lincoln, Benjamin, American general: b. Hingham, Mass., 24 Jan. 1733; d. there 9 May 1810. Until the age of 40 he followed the calling of a farmer, holding also at different times the offices of magistrate, representative in the provincial legislature, and colonel of militia. He was also an active member of the three provincial congresses of Massachusetts, and as militia officer displayed an efficiency which procured his promotion in 1776 to the rank of major-general. In this capacity he became favorably known to Washington during the siege of Boston. In the beginning of 1777 he joined Washington at Morristown with a new levy of militia, and soon after, at the suggestion of the commander-in-chief, was transferred to the continental service with the rank of major-general. He was sent to join the forces assembled to oppose the progress of Burgoyne and during the battle of Bemis' Heights commanded inside the American works; and was severely wounded in the leg, and compelled for nearly a year to retire from service. In September 1778 he was appointed to the command of the southern army, and upon the arrival of Count d'Estaing cooperated with the French troops and fleet in the unsuccessful assault on Savannah. From the unwillingness of his allies to continue the siege he was obliged to return to Charleston, where in the spring of 1780 he was besieged by a superior British force under Sir Henry Clinton. After an obstinate defense he was forced in May to capitulate, and retired to Massachusetts on parole. In the spring of the succeeding year he was exchanged, and subsequently participated with credit in the siege of Yorktown. In consideration of his merits and misfortunes Washington appointed him to receive the sword of Cornwallis upon the surrender of the British forces. He held the office of secretary of war 1781-3, and in 1787 commanded the forces which quelled the Shays' Rebellion in western Massachusetts, and in the same year was elected lieutenant-governor of the State, which office he held one year. He was collector of Boston 1789 till about two years before his death. He was a member of the commission which in 1789 formed a treaty with the Creek Indians, and of that which in 1793 unsuccessfully attempted to enter into negotiations with the Indians north of the Ohio. See life by Bowen in Sparks' 'American Biography' (2d series, Vol. XIII., 1847).

Lincoln, Charles Perez, American lawyer: b. Quincy, Mich., 7 Oct. 1843. He was educated at Hillsdale College; entered the Union army at the beginning of the Civil War, and served until mustered out of the service in June 1864. He was

admitted to the bar in 1871; was consul at Canton, China, 1875-81, and then began to practise his profession in Washington. He was elected commander of the Department of the Potomac, G. A. R., in 1888; and was 2d deputy commissioner of pensions 1889-93.

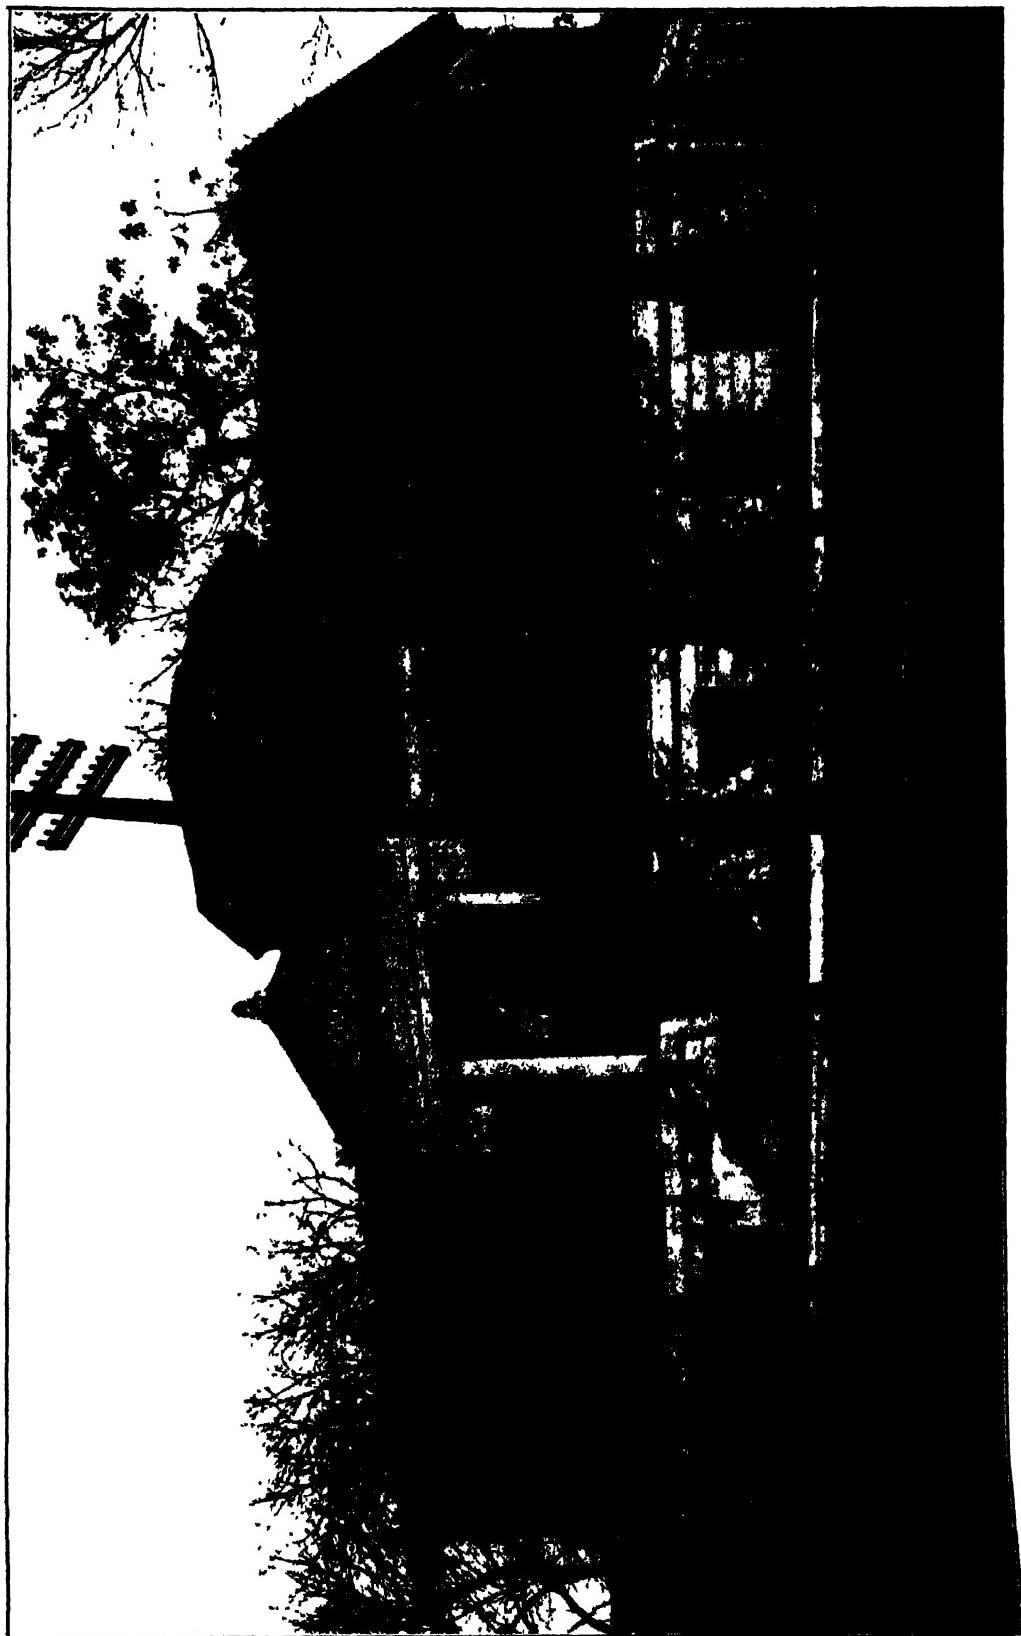

Lincoln, David Francis, American hygienist: b. Boston, Mass., 4 Jan. 1841. He was graduated at Harvard University in 1864 and at its medical school in the same year; and served as acting assistant surgeon in the United States navy during part of the Civil War (1864-5). He has published 'Electro-Therapeutics' (1874); 'School and Industrial Hygiene' (1880); 'Hygienic Physiology,' a school text-book (1893); 'Sanity of Mind' (1900), etc.

Lincoln, Jeanie Gould, American novelist: b. Troy, N. Y. She was married in 1877 to N. S. Lincoln of Washington, D. C., and has published 'A Chaplet of Leaves,' verse (1869); 'Marjorie's Quest' (1872); 'Her Washington Season' (1884); 'A Genuine Girl' (1886); 'An Unwilling Maid' (1897); 'A Pretty Tory' (1899).

Lincoln, Mary Johnson Bailey, American household economist: b. South Attleboro, Mass., 8 July 1844. She was educated at Wheaton Seminary, Norton, Mass., in 1864, was married to David A. Lincoln (now dead) in 1865, and since 1879 has been prominent as a lecturer and writer on household matters. She was the first principal of the Boston Cooking School, and is the culinary editor of the 'American Kitchen Magazine.' She has published 'The Boston Cook Book' (1884); 'Peerless Cook Book' (1886); 'Carving and Serving' (1886); 'The Boston School Kitchen Text Book' (1888).

Lincoln, Robert Todd, American diplomatist: b. Springfield, Ill., 1 Aug. 1843. He is the eldest son of Abraham Lincoln, and was graduated at Harvard College in 1864. He entered the Harvard Law School, but left it for the army and served on the staff of General Grant as captain. On the close of the War he resumed his legal studies and was admitted to the Chicago bar in 1867. He was secretary of war 1881-85; and although mentioned as a candidate for the presidency in the last-named year declined to allow his name to be placed in opposition to that of President Arthur. He was minister to Great Britain in 1889-93, and became president of the Pullman Palace Car Company in 1897.

Lincoln, England, an episcopal city and civic county, the capital of Lincolnshire, on the Witham, at the junction of several railroads, 120 miles north of London. It dates from pre-Roman times, was the Roman 'Lindum Colonia,' and at the time of the Norman Conquest, a fortified town of considerable importance. The principal edifice is the cathedral, crowning a height, on the summit and slope of which the town is built, 200 feet above the river. The cathedral dates from the 11th century and is chiefly early English but with interesting transitional phases, which are also to be seen in the various parish churches, the majority of which have undergone modern restoration. Other prominent buildings are the mediæval guildhall, the remains of the Norman castle, the ancient episcopal palace, the fine old Roman gateway spanning Hermin street, a theological college, school of

LINCOLN

art, and several benevolent institutions. The manufacture of machinery and agricultural implements forms the chief branch of industry. Pop. (1901) 48,784.

Lincoln, Ill., city, county-seat of Logan County; on the Illinois Central, the Peoria, D. & E., and the Chicago & A. R.R.'s; about 28 miles northeast of Springfield and 135 miles southwest of Chicago. The place was settled in 1835 and incorporated in 1865. It is situated in an agricultural region, and extensive deposits of coal are in the vicinity. The chief manufactures are cellulose, horse-collars, flour, mattresses, caskets and coffins, excelsior. The farm and dairy products and the coal mines contribute to the wealth of the city. Lincoln is the seat of the State Institution for Feeble-Minded Children; and of the Lincoln University, opened in 1865 under the auspices of the Cumberland Presbyterians. It has a free public library, the building a gift from Andrew Carnegie; a Deaconess Home and Hospital, Saint Clara's Hospital and Odd Fellows' Orphans' Home. Pop. 1890) 6,725; (1900) 8,962.

Lincoln, Kan., city and county-seat of Lincoln County; on the Saline River, and on the Union Pacific railroad; about 155 miles west of Topeka and 105 miles west of Wichita. It is in an agricultural region in which are raised large quantities of wheat and corn and a number of cattle. Limestone quarries in the vicinity contribute to the industrial wealth of the city. The industries and trade are connected chiefly with farm and dairy products and with live-stock. Pop. (1900) 1,262.

Lincoln, Neb., city, capital of the State and county-seat of Lancaster County; on the Chicago, B. & Q., the Chicago, R. I. & P., the Union P., the Missouri P., the Chicago & N. W., and other railroads; about 55 miles west of the Missouri River, and about the same distance north of the Kansas State line. The city, located in the midst of a fertile agricultural district, in the Salt Creek basin, at an elevation of 1,045 feet, rises gradually to the south and east, leaving the creek to the west and north. The location of the capital at this point was due in part to the numerous radiating branches of Salt Creek, but more especially to the saline springs which in early days furnished salt to the Indians and the buffalo, and later to the overland emigrants, and the early settlers of Nebraska. The site selected by a commission, 14 Aug. 1867, was surveyed the same fall; and, from the proceeds of lots sold at auction, the first capitol, the insane asylum, and the original university building were erected and completed by 1871.

Lincoln bids fair to fulfil the prediction of its founders by becoming a great railroad centre, as it already has 12 radiating lines, owned by five of the great corporations that now dominate in the West as already mentioned. With one exception each railroad has its own station and yard. The Chicago, B. & Q. repair and construction shops, employing 500 skilled mechanics, are located at Havelock, a suburb of Lincoln. Thirty-eight passenger trains enter, and the same number leave, Lincoln every 24 hours. Lincoln's railroad connections make it the great convention centre of the State.

The Name.—The names of Lincoln and Douglas are strangely associated in Nebraska history. The site selected for the capital in 1867 and named Lincoln is practically identical with the one proposed 10 years earlier to have been called Douglas. Thus the author of the law organizing the Territory of Nebraska failed to have his name perpetuated in its capital, but yielded that honor to his great rival.

Internal Appearance.—Lincoln is laid out, like most western cities, on the checker-board plan, with streets 100 or 120 feet in width. These broad streets are in general lined with trees and flanked with large lawns. The city contains an unusually large number of comfortable homes, excelling in this respect its development in business blocks. About 20 miles of the streets are paved—12.2 miles with brick, 3 miles with asphalt, and 5 miles with nearly worn-out cedar blocks. The waterworks are owned by the city; 50 miles of mains distribute the water from two deep wells, from which about 1,500,000 gallons of the very purest water are pumped per day. There are 40 miles of sanitary and 6 miles of storm-water sewers in the city.

The Lincoln Traction Company operates 37 miles of tracks, furnishes heat through conduits to the central section of the city, electric power and lights to public and private consumers, employs 100 men, and is capitalized at \$1,000,000. The following statistics suggest the character of the Lincoln Gas and Electric Light Company: 260,000 feet gas mains, 262,000 feet electric wire lines, 200 employees, and a capitalization of \$2,250,000. There are two telephone systems: one—"the Nebraska," in operation with 3,500 phones in use, and 140 employees; the other—"The Lincoln" (automatic), begins service 1 Jan. 1904, with 3,000 subscribers, and an investment of \$400,000. The city uses for municipal lighting 314 gas lights and 27 electric arcs.

Industries.—Manufacturing is of course yet in its infancy, but the total output per year will approximate \$5,000,000; in 1900 by United States census, \$4,105,951. A few industries are however well established. The making of leather goods, such as horse-collars, harness, etc., is not equaled west of the Missouri River. The production of oils and paints, mattresses and bed-springs, overalls and shirts, is large and developing rapidly. A large butter and creamery station is located at Lincoln. It receives cream from some 200 sub-stations, and makes two car-loads of butter per day. The jobbing and wholesaling industry is well under way, and in a few lines has reached creditable proportions. Lincoln, with 22 branch houses, is the largest distributing centre for farm machinery in the West. The jobbers in butter and eggs, fruits and groceries, are doing a good business. There is also a fair beginning in hats, hardware, drugs, furniture, coffins, paper, sash and doors, iron for plumbing, jewelry, crockery and queensware, lumber and coal. Two fair-sized grain elevators have recently been constructed. Total estimated business of jobbers and wholesalers for 1902, \$18,000,000. Lincoln is also becoming quite a centre for insurance business. Two strong life insurance companies, two fire insurance, three fraternal companies, including the Modern Woodmen with head-

LINCOLN—LINCOLN MEMORIAL UNIVERSITY

quarters here, and several mutual companies indicate the scope of development.

The banking capital is small for a city of its size: five commercial banks, capital \$500,000, surplus \$180,000, and deposits \$5,115,000, and one savings bank, deposits \$140,000, supply the business community.

Public Institutions.—The State fair grounds, the penitentiary, one of the insane asylums, and the Home of the Friendless are located in or near the city. The other public buildings are: the Capitol, costing \$750,000; the county courthouse, \$200,000; the United States post-office, \$150,000. The post-office becomes the city-hall, at a cost to the city of \$50,000, on the completion of the new Federal building for which Congress has appropriated \$350,000. The Carnegie library, \$75,000 and the grounds; 19 public school houses that cost from \$15,000 to \$50,000 each. Saint Elizabeth's Hospital, \$150,000, the Catholic Orphans' Home, and the Tabitha Home,—private institutions,—aid in caring for the sick and unfortunate. The mineral waters are used in several private sanitariums.

Amusements.—Outdoor—one small public park, the university athletic field, the Epworth Assembly park, and the "Country Club" grounds afford meagre facilities. The city supports one theatre and an auditorium.

Government.—The charter, granted by the legislature, contains no marked elements of interest. A mayor with large powers, a council of one house, and an excise board of three members, with the usual executive officials, control the city's public affairs. Taxes are 10 mills on the dollar of assessment, the last valuation showing the wealth of the city to be \$22,380,834. The total bonded debt is \$1,169,100, excluding about \$220,000 of paving bonds payable by abutting private property.

Education.—Lincoln is at present rather an educational than a business centre. Its population is largely American, representative of the North and Middle West. Neither great wealth nor extreme poverty is found. The public schools are efficient, and enroll 6,210 students. The high school employs 36 teachers, and registers 1,090 pupils, a number claimed to be unsurpassed by any city of its size. There are three musical conservatories, three universities, three colleges, one preparatory school and two parochial high schools, which tend to give a distinct educational tone to the public as well as private life of the city. The largest and most important educational institution is that of the State University and Agricultural College (q.v.). The campus contains 12 acres, and 8 buildings; there are two more under construction at cost of \$110,000. The farm of 320 acres has barns, dairy buildings, recitation halls, besides new buildings in course of construction, at a cost of \$100,000. (The legislature of 1903 appropriated in all \$824,000 for the biennium.) The calendar of 1902-3 shows 2,560 students in attendance. The Wesleyan University (q.v.), situated in University Place, a suburb of Lincoln, ranks next in importance, and enrolled 1902-3, 650 students. A third building is in course of construction. Union College (q.v.), a Seventh Day Adventist school, with three buildings and over 400 students, and Cotner University (q.v.), controlled by the Christian Church, with one good building and 200 stu-

dents, are prospering. The conservatories and other schools add several hundred more students to this list. The public libraries are: the University, 60,000 volumes; the State, 40,000; the City, 15,000; and the high school, 2,500. Lincoln's educational output is indicated in the second-class mail matter sent through its post-office. One per cent of all the second class mail matter of the United States originates in Lincoln. It requires 75,000 mail sacks to carry this matter for one year. In 1902 4,894,835 pounds of second class mail matter left the city. In all 66 publications are entered, one with 750,000 circulation, two others with about 150,000 each, and a fourth with over 100,000.

Religion.—There are 30 church buildings in Lincoln. The following organizations are represented: Methodists, 3 organizations; Congregational, 8; Presbyterian, 3; Christian, Baptists, Lutheran, Episcopal, Catholic, 2 each; United Presbyterian, Jews, Christian Science, Unitarian, Reformed, Swedish, Free-will Baptists, and several minor denominations, 1 each. There are 3 colored churches. The leading denominations all have exceptionally fine buildings.

Population.—Lincoln's growth has been somewhat irregular, yet counting decades gradual, Lincoln in 1867—then called Lancaster—contained only one store and some half-dozen dwellings. By 1870 it contained 2,441 people. In 1880, 13,004. The padded census of 1890 gave the city 55,154 population—a number too large by at least 20,000. In 1900 it had 40,169, and has grown rapidly since.

HOWARD W. CALDWELL,
Of the University of Nebraska.

Lincoln, Mount, one of the peaks of the Rocky Mountains; about 8 miles northeast of Leadville. Its height is 14,297 feet. A meteorological station is on the summit, and another on the lower level (13,500 feet). A railroad has been constructed to the silver-mining works at the summit.

Lincoln College, established at Lincoln, Ill., in 1866, under the auspices of the Cumberland Presbyterians. It has a preparatory department, and the college courses lead to the degrees of A. B., B. S., and B. L. In 1903 there were connected with the college 12 professors and instructors and 200 students. The library had about 3,500 volumes; the grounds, buildings, and apparatus were valued at nearly \$80,000; the productive funds were \$65,000; and the income from productive funds, tuition, and other fees, amounted to about \$6,000.

Lincoln Memorial University, a coeducational institution, at Cumberland Gap, in Claiborne County, Tenn. The university was chartered in 1897, but was not opened until the buildings were in such a condition as to accommodate pupils. The situation of Cumberland Gap (q.v.) makes it easy of access for students from Tennessee, Virginia, and Kentucky, and it is not far distant from West Virginia and North Carolina. Prior to the opening of this school there was within a radius of 50 miles fully 250,000 people without any well-equipped college, and except in a few places, no well equipped elementary school. The plan of the work is to maintain an institution which "shall promote research, investigation, and experiment for the ex-

LINCRUSTA-WALTON—LINDEN

tension and application of knowledge, and shall impart such instruction in the various branches of education as will tend to promote good society and good citizenship, and the ability to develop the abundant resources of the Southern States." The plan of erecting such a school was first started by Gen. O. O. Howard, of Burlington, Vt., who desired to see a school established some place easy of access for the mountaineers of this locality, because of the great interest which Abraham Lincoln had in the people of this section. The institution comprises three departments: the academic, the normal, and the industrial. There are several grades in the academic department. In the normal department teachers are trained; and in the industrial department, agriculture, carpentry, masonry, typesetting, and other trades, are taught to the boys and young men, and domestic science to the girls and young women.

The university owns 600 acres, and the buildings cost \$150,000. They include class rooms, saw-mills, shingle-mills, shops, etc. Andrew Carnegie contributed \$13,800. The present endowment fund is \$200,000. By working for the school in some of the industrial departments, the students can earn their tuition and board, or at least a part of the cost of their education.

Linrusta-Walton. See LINOLEUM.

Lind, Jenny (MADAME GOLDSCHMIDT, gold'shmit). Swedish singer: b. Stockholm 6 Oct. 1820; d. Malvern, England, 2 Nov. 1887. In very early childhood she displayed the faculty of tune and of musical memory in such degree as to attract observation, and at 9 her voice was considered so remarkable that she was admitted to the Stockholm Conservatory of Music as a pupil of Creelius and Berg. In spite of an apparent lack of individual attractions, which led the manager of the court theatre at first to demur, when he had heard her sing she was entered at the vocal school there, made rapid progress, and up to the age of 12 was frequently heard on the local stage. After years of thorough study and voice-building, in 1838 she made her debut, with great success, as Agathe in "Der Freischutz." As operatic star in Stockholm and other cities in Sweden and Norway, she extended her fame, and in 1841 studied for the greater part of the year in Paris under Manuel Garcia. She went to Berlin in 1844, studied German, and in Meyerbeer's "Feldlager in Schlesien" appeared as Vielka. During the next year she made a Continental tour which established her in a position of supremacy, her great successes being won in Dresden, Leipsic, etc., and finally in Vienna. In 1847 she made her first appearance in England, which was followed by a succession of unprecedented triumphs. Her tour of the United States (1850-2) brought her not only fresh honors, but also large financial returns, and is remembered to this day by many who shared in the material and spiritual benefits which her noble womanhood and artistic genius conferred. In 1852 she was married in Boston to Otto Goldschmidt (q.v.), then conducting the Bach choir, and virtually retired from her profession, though subsequently reappearing on special occasions. She returned to Europe; at length settled in London; and made her last public appearance at Düsseldorf in 1870. In 1894 a bust of her was unveiled in Westminster

Abbey. Consult: Rockstro and Holland, "Jenny Lind the Artist" (1891); Rockstro and Goldschmidt, "Jenny Lind, Her Vocal Art and Culture" (1894).

Lindau, lin'dow, Paul, German author: b. Magdeburg 3 June 1839. He studied philosophy and literature at Halle, Paris, and elsewhere, in 1872 established "Die Gegenwart," a weekly literary and political journal, and in 1878 "Nord und Süd," a monthly. Among his earliest works were pleasantly written books of travel, "Venice" (1864), "Paris" (1865), and later "The New World" (1884). But he is better known as a playwright and novelist, his subjects being taken almost exclusively from modern life. The most successful of his plays was possibly "Maria and Magdalena." His novels include: "Herr und Frau Bewer"; "Toggenburg" (1883); "Mayo," a romance cycle; "Berlin" (1886-90); and "The Brothers" (1894). In 1895 he became manager of the court theatre at Meiningen.

Lin'den, or Basswood, a genus of trees (*Tilia*) of the order *Tiliaceæ*, ordinarily known as basswoods in the United States. The species, of which there are about a dozen, are natives of the northern temperate zone, and more or less resemble each other in general appearance. They are characterized by alternate, usually heart-shaped, leaves with toothed edges; small yellowish, often fragrant, flowers in cymes; the peduncles of which are attached to membranous bracts; and globular nut-like fruits about the size of peas. The trees, in many horticultural varieties, are widely planted in Europe, where they are known to the English as limes, and have been introduced into America for their pleasing form and dense shade, and to some extent also because of their abundant yield of nectar, from which bees make one of the finest qualities of honey. They are also planted for their timber, usually called "whitewood," which is highly valued on account of its whiteness, lightness, toughness, and durability, and is used for turned and carved ornaments, and for making honey-boxes and other light articles the whiteness of which is desired to enhance the appearance of the goods they contain; also extensively used for carriage bodies, cabinet work, and interior parts of furniture. It makes a high grade of charcoal, used by druggists, gunpowder-makers, and artists. The fibrous inner bark is made into mats and cordage, and strips of it are widely used for tying plants, etc. When stock-food is scarce in early spring the twigs and budding shoots are often fed to farm animals, being very mucilaginous and nutritive, though liable, it is said, to injure the quality of butter made from the milk of cows fed upon them. The best-known species are the American basswood (*T. americana*), a stately tree often exceeding 75 feet in height and 10 feet in girth. Its range extends from New Brunswick to Minnesota and southward to the elevated lands of Georgia and Texas. In the more thickly settled parts of this region it is becoming scarce as a timber tree because of the great demand for its wood. In America it is the most frequently planted species. Owing to confusion in nomenclature, the name "European linden" is applied to at least three species, *T. platyphyllos*, *T. vulgaris*, and *T. ulmi-*

LINDLEY—LINDSEY

folia. The first is most widely planted in America. The last is very late in blossoming and should be more extensively cultivated in order to extend the season of honey production. Linden all thrive best upon good land. They are easily propagated from seeds, layers, and grafts, and by "stooling," the small trees being cut down close to the ground, the sprouts covered with soil, and when rooted removed to nursery rows.

In some countries the fibrous inner bark of the linden is separated by soaking in water, and manufactured into fishing-nets, mats, shoes, and clothing; and the cordage made from it is said to be remarkably strong and elastic. (See *BAST*.) The wood is sometimes cut into thin strips and used in the manufacture of chip hats, which resemble those made of straw.

Lindley, lind'lī, John, English botanist and horticulturist: b. Catton, near Norwich (Norfolk), 5 Feb. 1799; d. Acton 1 Nov. 1865. He became Belgian agent for a London seed merchant in 1815, later took up botanical studies, published in 1819 a translation of Richard's 'Analyse du Fruit,' and was appointed assistant librarian to Sir Joseph Banks at London. Later, he was successively made assistant secretary to the Horticultural Society (1822-41), professor of botany in the University of London (1829-60), and lecturer in botany to the Apothecaries' Company (1836-53). In 1828 he was elected to the Royal Society, whose royal medal he received in 1857, and in 1853 became a corresponding member of the Institut de France. He was appointed editor of the 'Botanical Register' in 1826, of the 'Journal of the Horticultural Society' in 1846; and in 1841 was a founder of the 'Gardeners' Chronicle,' whose chief editor he was until his death. He was an able lecturer, a constant opponent of the Linnaean as contrasted with the natural system of classification, and the author of several valuable works such as: 'The Theory and Practice of Horticulture' (1842), and 'The Vegetable Kingdom' (1846). He also wrote almost the entire descriptive portion of London's 'Encyclopædia of Plants' (1822-9).

Lindsay, lin'zā, Anna Robertson Brown, American author: b. Washington 20 Feb. 1864. She was graduated from Wellesley in 1883, subsequently studied mediæval literature at Oxford University, and was married to S. M. Lindsay (q.v.) in 1896. She has published: 'What is Worth While?' (1893); 'The Victory of Our Faith' (1895); 'Culture and Reform' (1896); 'Giving What We Have' (1897); 'What Good Does Wishing Do?' (1898); 'The Warriors' (1903).

Lindsay, or Lyndsay, lind'zā, Sir David, Scottish poet, usually described as "of the Mount" (an estate near Cupar in Fife): b. about 1490; d. 1555. He studied in the University of St. Andrews, and in 1509 became page of honor to James V., then an infant. In 1528 he produced his 'Dreme,' and in the following year presented his 'Complaynt' to the king. In 1530 he was inaugurated Lyon king-at-arms, and knighted, and in 1531 sent on a mission to Charles V. He published a drama entitled 'A Satyre of the Three Estatis,' played at court in 1539, and followed in 1536 by his 'Answer to the King's Flyting'; and by his 'History and Testament of Squire Meldrum'

(1538). His last work, 'The Monarchie,' was finished in 1553. For more than two centuries Lindsay was the most popular poet in Scotland. His satirical attacks on the clergy in some degree paved the way for the Reformation.

Lindsay, Harry. See *Hudson, H. L.*

Lindsay, Samuel McCune, American political economist and educator: b. Pittsburg, Pa., 10 May 1869. He was graduated from the University of Pennsylvania in 1889, and took post-graduate courses there and abroad. After his return to the United States he was appointed assistant professor of sociology at the University of Pennsylvania; he has also been editor of the department of sociological notes in the 'Annals of the American Academy of Political and Social Science' (1895-1901), and associate editor of the 'Annals.' In 1892 he was special agent of the United States Senate Finance Committee to report on wholesale prices in Europe; in 1899-1900 was expert of the Industrial Commission to report on railroad labor; and in 1902 was appointed commissioner of education to Porto Rico, being granted leave of absence from the University of Pennsylvania. He has written 'Railway Labor in the United States' (1902); 'Social Work at the Krupp Foundries'; 'The Study and Teaching of Sociology'; 'The Unit of Investigation in Sociology'; and other articles in the 'Annals of the Academy of Political and Social Science'; 'Report on Education in Porto Rico'; and other monographs.

Lindsay, William, American lawyer: b. Rockbridge County, Va., 4 Sept. 1835. He was educated in his native State; removed in 1854 to Clinton, Hickman County, Ky., where, after teaching school and studying law, he was admitted to the bar in 1858. Throughout the Civil War he served in the Confederate army, rising to the rank of captain and acting as a staff officer, and after the war returned to Clinton and resumed the practice of law. In 1867 he was elected State senator as a Democrat; in 1870 took his seat on the bench of the supreme court of Kentucky; and was chief justice of the State 1876-8, declining a renomination and returning to the practice of law at Frankfort. In 1889 he again entered the State senate; in 1893 served as commissioner of the World's Columbian Exposition; in the same year was elected to the United States Senate for the unexpired term of John G. Carlisle, who had resigned to become secretary of the treasury; and in 1894 he was re-elected, but differed with his party on the money question, and toward the end of his term usually voted with the Republicans. After leaving the Senate he went to New York city and once more resumed the practice of law. In 1901 he was appointed by President McKinley a commissioner for the Louisiana Purchase Exposition at St. Louis.

Lindsay, Ontario, Canada, the capital of Victoria County, a town and port of entry on the Scugog River, at the junction of branches of the Grand Trunk railroad, 57 miles (by rail) northeast of Toronto. It has important lumber interests, saw and grist-mills, tanneries, carriage works, manufactures of agricultural implements, and carries on a considerable river, canal, and lake traffic. Pop. (1901) 7,003.

Lindsey, lin'zi, William, American merchant and author: b. Fall River, Mass., 12 Aug.

LINDSBORG—LINEN

1858. He engaged in business in 1877, and after removing to Boston, in 1886, devoted his leisure to writing. He has published 'Apples of Istan-khar' (1895), a volume of poems; and 'Cinder-Path Tales' (1896), stories of athletic sports.

Lindsborg, līnz'bōrg, Kan., city, in McPherson County; on the Smoky Hill River, and on the Missouri Pacific and the Union Pacific R.R.'s; about 115 miles southwest of Topeka, and 64 miles north by west of Wichita. It is in an agricultural region, and its trade is chiefly in live-stock, grain, broom-corn, flour, and dairy products. It has large brick and lumber yards and grain elevators. An important industrial establishment is the Bethany Book Concern, the Western publishing institution for Lutheran literature. There are a number of Swedish Lutherans in Lindsborg. It is the seat of Bethany College, opened in 1881 under the auspices of the Lutherans. Among its departments, that of music is well known for its annual concerts, when the students render the 'Messiah.' Pop. (1900) 1,279.

Lindsley, līnz'lī, John Berrien, American educator: b. Princeton, N. J., 24 Oct 1822; d. 7 Dec. 1897. He was graduated from the University of Nashville in 1839 and received his degree in medicine at the University of Pennsylvania. Studying theology, he was ordained to the Presbyterian ministry in 1846 and preached for several years. He became professor of chemistry in the University of Nashville in 1850, and was chancellor of the institution 1853-73. He was likewise professor of chemistry in the University of Tennessee 1880-97, and of *materia medica* in the Tennessee College of Pharmacy 1896-7. He published 'Our Ruin: its Causes and Cure' (1868); 'The Military Annals of Tennessee' (1886).

Line, Mathematical. In geometry, a line may be defined (1) as the locus described by a moving point; (2) as a magnitude which, at each of its points, has extension in one direction only; (3) as the boundary which separates two contiguous parts of a surface; or (4) as the intersection of two surfaces, or of a surface with itself. Each of these definitions has its own merits, and geometers use one or another of them, according to convenience.

In physics, "lines" of various kinds are constantly referred to, but in many cases the context sufficiently indicates the sense in which the word is used. A "line of force," in a field of electric or magnetic force, for example, is a line whose direction, at every point, coincides with the direction of the force at that point. The field is conceived to be filled with such lines, so that through every point of the field one such line passes, and only one. In the mechanical theory of heat (see THERMODYNAMICS) the state of a homogeneous body, with respect to its temperature, to the pressure exerted upon it, and to the volume occupied by a unit of its mass, is often represented by means of a diagram in which two of these quantities are taken as abscissa and ordinate, respectively. In such a diagram an "isothermal" line is a line along which the temperature of the body remains constant; an "adiabatic" (or "isen-tropic") line is one which is so drawn that if the body should pass through the succession of states that the line represents it would not at

any moment either absorb or emit heat. An "isopiestic" (or "isobaric") line is a line along which the pressure to which the body is exposed remains constant. An "isometric" line is one along which the volume of the body remains constant.

In steam engineering the various parts of the diagram that is drawn by an indicator are designated as "lines," although they are but the several parts of a single line. Thus the "admission line" is that part of the diagram which the indicator draws while steam is being admitted to the cylinder; the "expansion line" is that part drawn while the steam in the cylinder is expanding; the "exhaust line" is that part drawn while the cylinder is in free communication with the atmosphere (or with the condenser); and the "compression line" is that part which the indicator draws after the exhaust valve has closed, and before the admission valve from the boiler opens again. The "atmospheric line" upon such a diagram is the line that the indicator draws when disconnected from the engine, and in free communication with the atmosphere.

Line of Beauty, in art, an ideal line frequently represented in the form of a very slender elongated letter S.

Linen, a cloth of very extensive use, made of flax, and differing from cloths made of hemp only in fineness. Hemp is in part now used in manufacturing cloths which are called linen, although the coarser hempen fabrics, as canvas, sail-cloth, etc., do not bear that name. In common linen the warp and woof cross each other at right angles; if figures are woven in it is called damask (q.v.). The species of goods which come under the denomination of linen are table-cloths, plain and damasked, cambric, lawn, shirting, sheeting, towels, etc. Linen cloth, or cloth woven of combinations of cotton or other textile fabrics with linen, is printed in the same manner as calico. Fancy cloths are also made by weaving with yarns dyed of various colors, and sometimes with printed yarns. Linen is extensively manufactured in England, Scotland, and Ireland. It is also a staple in various parts of Europe.

The beauty of linen consists in the evenness of the thread, its fineness and density. The last of these qualities is sometimes produced by subjecting it to rolling, hence linen with a round thread is preferred to that with a flat thread. The warp or woof is not unfrequently made of cotton yarn, which renders such stuff, called union cloth, less durable. In a historical view linen is interesting from its use by several nations in their religious ceremonies. The Egyptian and Jewish priests wore it at all their religious ceremonies, hence the former are styled by Ovid and Juvenal, "linen-wearing." Linen was an article of export from Egypt in the time of Herodotus. From Egypt the use and manufacture of linen probably passed to the Greeks and Romans, but the use of linen did not become common at Rome till late in the history of the republic. The Roman priests wore linen garments at that time. Among the Greeks a linen tunic was a regular part of the male costume as early as the Homer period. Linen was also used as a material for writing, as shown by the Roman *libri linteui*, "linen books." The mummy bandages, covered with hieroglyphics,

LINES — LINGULA

are also proofs of this use of linen. In the Middle Ages linen and woolen cloth formed the chief materials for dress, and fine linen was held in very high estimation. Germany and Brabant then carried linen manufactures to the greatest perfection.

The weaving of linen has been practised in Great Britain for a very long period, beginning with the Anglo-Saxon times, but though the manufacture has been much extended since the introduction of machinery, its expansion is limited by the greater cheapness and convenience in many respects of cotton. The English linen industry owed much to Flemish weavers, who settled in England at various times from the 11th or 12th century onward. The chief seat of the English linen manufacture is Leeds and its neighborhood, where spinning is carried on on a very extensive scale. A single room in one of the factories at Leeds is said to cover two acres. Ireland and Scotland, however, are much larger manufacturers of linen than England.

Linen was woven in Ireland as early as the 11th century. The manufacture was improved by the refugees who left France on the revocation of the Edict of Nantes, and it was patronized by the Duke of Ormonde. The manufacture never really flourished till it was carried on in mills, and by the aid of machinery. The value of linen goods now exported from Ireland to Great Britain is estimated at about \$50,000,000 annually.

Dundee is the seat of the Scotch linen manufacture, and its progress there has been extraordinary. The manufacture appears to have been introduced into Dundee some time about the beginning of the 18th century. In 1745 only 74 tons of flax were imported without any hemp, the shipments of linen cloth during the same year being estimated at about 1,000,000 yards. In 1791 the imports of flax amounted to 2,444 tons, and those of hemp to 299 tons; the exports that year being 7,842,000 yards linen, 280,000 yards sail-cloth, and 65,000 yards bagging. From this period the trade began to extend itself gradually, though not rapidly.

The introduction of machinery in the linen manufacture is of recent origin. It followed the adaptation of machinery to the manufacture of cotton, but as there were some special difficulties to be overcome, an interval took place between the invention of the various cotton machines and their adaptation to the linen manufacture. The machinery used both in spinning and weaving linen is in general, however, the same as that used for cotton. See TEXTILE INDUSTRY, AMERICAN.

Lines, Edward Stevens, American Protestant Episcopal bishop: b. Naugatuck, Conn., 23 Nov. 1845. He was graduated from Yale in 1872 and after two years spent in the Berkeley Theological School, at Middletown, Conn., was ordained in 1874. He was rector of Christ Church, West Haven, Conn., 1874-9 and of St. Paul's Church, New Haven, 1879-1903. In November 1903, he was consecrated bishop of the diocese of Newark, which comprises the northern half of New Jersey.

Lines of Force. See FORCE.

Ling, a sea-fish (*Lota molva*), resembling a pike in shape and 3 to 4 feet long, but a member

of the cod family (*Gadidae*). It abounds around the British coasts; its fishery approaches in importance and resembles in methods that for cod. Great quantities are preserved by drying, salting, etc.; and an excellent oil is extracted from the liver.

The name is also given to the eel-pout or burbot, another species (*L. vulgaris*) so-called not only in Europe but in northern New York. See Burbot.

Linga, ling'ga, an emblem commonly used in the sectarian worship of the Hindus. It represents the male or generative power of nature. Originally of an ideal and mythical nature, it has degenerated into practices of the grossest description; thus taking the same course as the similar worship of the Chaldaeans, Greeks, and other nations. The manner in which the linga is represented is generally inoffensive—a pillar of stone or other cylindrical objects being held as appropriate symbols of the generative power of Siva. Its counterpart is "Yoni," or the symbol of female nature productive. See also SIVA.

Lingard, ling'gärd, John, English historian: b. Winchester 5 Feb. 1771; d. Hornby, Lancashire, 17 July 1851. He was educated for the Roman Catholic priesthood at Douay, was ordained in 1795 and was first stationed at Newcastle-upon-Tyne. Here he published in 1805 'Catholic Loyalty Vindicated.' His next work of importance was 'Antiquities of the Anglo-Saxon Church.' His greatest work, the 'History of England from the Invasion of the Romans to the Year 1688,' printed in 8 vols. (1819-30), reached a fifth edition in 1850, when it appeared in 10 vols. It has since been regarded as a valuable work of reference by historians of all parties. It possesses for Protestant historians the valuable quality of giving the views on controverted points of an able and well-informed Catholic writer. The 1850 edition of the history was elaborately revised by the author. Apart from the sympathies of the writer, the work is universally regarded as one of high authority. He refused a cardinal's hat offered him by the pope, but accepted a pension of £300 a year from the queen.

Lingayén, lin-gä-yän', Philippines, a pueblo and the capital of the province of Pangasinán, Luzon, situated on an island of the delta of the Agno River, formed by one of the outlets of the river and the Gulf of Lingayén. It has a fine parish church and the buildings generally are well constructed, many being of stone. The Manila and Dagupan railroad has a station within eight miles at Dagupan, and Lingayén is the converging point of several important highways and has frequent communication by water with Manila. It has therefore an important trade. Pop. 18,900.

Lingayén, Gulf of, an arm of the China Sea indenting the western coast of the island of Luzon, Philippines, north of Manila Bay. The width of the entrance from San Fernando Point to Santiago Island is 20 miles. The east coast is mountainous; the west coast is generally level and less elevated and is fringed by low wooded islands, the channels between which are navigable for native coasters. Typhoons are prevalent in September and October.

Lin'gula. See BRACHIOPODS.

LINIERS Y BREMONT — LINNET

Liniers y Bremont, Santiago Antonio María de, sán-té-ä'gō àn-tó-né-ô mà-ré-ä dà lén-é-ärs' è brá-mönt', Spanish naval officer: b. Niort (Deux-Sèvres), France, 6 Feb. 1756; d. near Buenos Ayres, Argentine Republic, 20 Aug. 1810. After the French Revolution he entered the Spanish naval service, in which he attained captain's rank. He defended Montevideo against the British in 1806, and in 1807 forced them to relinquish Buenos Ayres, which they had occupied. The ruling viceroy was then deposed by popular demand, and Liniers selected for the post (16 May 1808). The British soon attacked Buenos Ayres, and, 1 July gained a battle under its defenses; but Liniers successfully managed the resistance and the enemy, after a retreat and large losses, withdrew from the country. He was succeeded in 1809 by Cisneros, whose rule was followed by the revolution of 10 May 1810. Liniers thereupon marched from Cordobá to Buenos Ayres for the purpose of quelling the revolt; but was captured, and shot.

Linley, lin'li, Thomas, English composer: b. Wells 1732; d. London 19 Nov. 1795. He was a pupil of Chilcot at Bath and of Paradies at Naples, became one of the best English vocal instructors, and for several years directed the concerts at the Bath assembly-rooms. In 1774 he became joint director of the Drury Lane oratorios, in 1776 purchased Garrick's share in Drury Lane, and in 1776-91 directed the music there. His music contributed greatly to the success of Sheridan's "Duenna," which was performed 75 times during the season. He also composed the much admired accompaniments to the "Beggar's Opera," various other music for dramatic works, and glees, canzonets, and songs. He obtained high place among English composers through his simplicity and excellent taste.

Linlithgow, lin-lith'gō, Scotland, the county town of Linlithgowshire, 16 miles west of Edinburgh. It is an ancient royal burgh, with a fine 12th century Gothic church, and other historical edifices, chief of which is Linlithgow Palace (mostly rebuilt between 1425 and 1628), the birthplace of James V. and Mary Stuart. Pop. (1901) 4,279.

Linn, James Weber, American author and educator: b. Winnebago, Ill., 11 May 1876. He was graduated from the University of Chicago in 1897 and since 1899 has been instructor there. He has published "The Second Generation," a novel (1902); "The Chameleon" (1903).

Linn, William Alexander, American journalist: b. Sussex, N. J., 4 Sept. 1843. He was graduated at Phillips Academy, Andover, Mass., in 1864, at Yale in 1868, and in 1883 was admitted to the New York bar. From 1868 to 1891 he was engaged in newspaper work, during part of that time being on the staff of the New York *Tribune*, and was managing editor of the *Evening Post*, 1891-1900, resigning to devote himself to literary work. He was a member of the New Jersey commission of 1899, by which, together with the Interstate Commission, of which he is a member, the passage and enforcement of laws for the prevention of the destruction of the Palisades were secured. He is a contributor to agricultural and horticultural papers, and has also written "The Story of the Mormons" (1902); "Rob and His Gun" (1902); and "Horace Greeley" (1903).

Linnaeus, li-né'üs, Carolus, the Latinized form of the name of Carl von Linne, Swedish botanist: b. Rashult, Småland, 12 May 1707; d. Upsala 10 Jan. 1778. He showed an early interest in botany; entered the University of Lund, where his botanical tastes were encouraged by Kilian Stobæus, physician to the king, from whose library he was supplied with necessary books. In 1728 he went to Upsala, where he undertook the supervision of the botanic garden. Here he made the acquaintance of the botanist, Rudbeck, whose assistant he became, and assisted Olof Celsius in the preparation of the latter's "Hierobotanicon." Aided by the Academy of Sciences at Upsala, Linne made a journey about 4,600 miles through Lapland, the result of which was shown in his "Flora Lapponica," published 1737. In this year he went to the University of Harderwyk in Holland and took an M. D. degree, and later visited Leyden, where he published his first sketch of his "Systema Naturæ" and "Fundamenta Botanica." In 1736 he visited England, and in September 1738, settled in Stockholm as a physician. He slowly acquired a practice, was made naval physician of Stockholm, and obtained some minor appointments. He became professor of medicine at Upsala in 1740, and of botany in 1741. He was ennobled in 1737. During his professorship of botany he drew students from all over the civilized world, increasing the number attendant on the university from 500 to 1,500. The importance of Linnaeus' work can scarcely be overrated. It has been said that "he found biology a chaos; he left it a cosmos." He it was who established the systematic botany and zoology of modern times. He first announced the principles for the definition of genera and species, and established the binominal nomenclature of both. He was a careful observer, a methodical worker, and a clear and succinct writer. As a teacher he was of great influence in revolutionizing the methods of botanical study. He published more than 180 works, among which the most important are: "Systema Naturæ" (1735); "Fundamenta Botanica" (1736); "Genera Plantarum" (1737); "Flora Lapponica" (1737); "Classe Plantarum" (1738); "Philosophia Botanica" (1751); and, chief of all, "Species Plantarum" (1753).

Linnell, lin'el, John, English painter: b. London 16 June 1792; d. Redhill, Surrey, 20 Jan. 1882. He began his artistic career as a pupil of West and Varley and was for some time a successful teacher of drawing, numbering among his pupils Mary Wollstonecraft Shelley. He had painted from his 15th year confining himself exclusively to landscape. Between 1824 and 1838 he produced a number of excellent pictures in this class. Originally an imitator of Gainsborough, he soon developed a brilliantly original style. He was particularly successful in portraying the insular sky scenery of England with its varied cloud forms, and changing play of sunlight, and his works combine delightful freshness with supreme skill in handling. In the South Kensington Museum is one of his pictures, "Girls Gathering Flowers," and in the National Gallery are his "Wood Cutter," and "Windmill." Consult: Story, "Life of John Linnell" (1892).

Linn'et, a very common and attractive song-bird, one of the smaller migratory finches,

LINNET-HOLE—LINSEED OIL INDUSTRY

of southern Europe and adjacent countries of Africa and Asia. In autumn and winter the plumage is brown-streaked and dull, but in the spring molt, on the approach of the breeding season, the breast and head of the mature male become bright crimson. This gay dress is assumed and put off gradually, and bird-catchers speak of brown, gray, red or rose linnets as if they were separate species, but there is only one—*Linota cannabina*. The name refers to the fondness of the bird for hemp, flax-seed, and the like, formerly called the “lint” crops, whence comes the Scotch names “lintie,” “lintwhite,” etc., and the English “linnet.” The habits of these birds in the fields are much the same as those of their relatives the American goldfinches, or of the redpolls, called “linnets” in Canada. These are among the most prized of cage-birds for the sake of their song, and are taken in great numbers in traps as well as extensively bred. They will interbreed with the canary and an interesting and valuable hybrid has thus been produced. The song is loud, flute-like and exceedingly agreeable; it consists of several connected strains, and is esteemed by connoisseurs in proportion to the frequency with which certain clear sonorous notes, or “crows,” recur. It sings throughout the year, except when molting, and may be taught various airs and melodies not its own—even to imitate well the complicated song of the nightingale. Such education is rarely given it, however, except in Germany. The care and feeding of a linnet should be the same as those given a canary. See CANARY; CAGE-BIRDS.

Linnet-hole, in glass making, a table connecting the glass-melting furnace with the arch.

Lino'leic Acid, one of the constituents of linseed oil, obtained by saponifying the oil with soda, separating the soap, and decomposing it with chloride of calcium. After washing, the soap is treated with ether, which dissolves the linoleate of calcium. This salt is next decomposed with hydrochloric acid, and the linoleic acid taken up by ether. After distilling off the ether the oily acid remains, which is converted into a barium compound which is purified by crystallization, and from this the acid is finally got by addition of sulphuric acid. It is a pale-yellow oil, insoluble in water, but readily soluble in ether. It is lighter than water, has a slight acid reaction and harsh taste.

Lino'leum, a kind of floor-cloth introduced in England in 1860. It consists of a mixture of oxidized linseed oil and ground cork spread in a uniform layer upon canvas, the surface of which may be printed in patterns of different colors as in ordinary floor-cloth. The oxidizing of the linseed oil, by which process it becomes a caoutchouc-like substance possessing a certain amount of elasticity, is effected by exposing it in thin films to the influence of air. Certain proportions of kaurigum, rosin, and pigments, according to the ground color desired, are added to the oxidized oil, which is then intimately mixed with the ground cork, and firmly squeezed on and rendered adherent to the surface of a rough canvas backing, which is afterward coated or waterproofed with oil paint. An embossed linoleum, washable, waterproof and warm, invented by Frederick Walton as a substitute for wall paper, is named after him “Lincrusta Walton.”

Linosyris, in botany; *Goldylocks*; a genus of *Composites*, sub-order *Solidagineae*. The achenes are compressed and silky, the pappus in a double row pilose, the involucre of one row of scales, surrounded by several long ones, or imbricated; the florets all perfect, deeply five-cleft, yellow. Ten species known from Europe and the West of Asia.

Lin'otype, a machine, operated by finger keys, which automatically produces and assembles, ready for the press or stereotyping table, type metal bars, each bearing, properly justified, the type characters to print an entire line. The linotype is the invention of Ottmar Mergenthaler. Beginning in 1876, he perfected his device in 1886, the first newspaper to use it being the New York *Tribune*. The device has since been greatly improved by means of spacing facilities, etc., and is adapted for book work as well as for newspapers. Its manipulation may be roughly approximated to that of a typewriter. The linotype does not set type. It produces a slug or line of metal upon which the characters to be printed stand out after the fashion of reading matter for the blind. See COMPOSING MACHINES.

Lin'sang, one of the beautiful spotted civets of the Oriental genus *Prionodon*, of which various species are to be found from northern India to Borneo. The West African linsang (*Poiana poensis*) is a rare species from the Fernando Po district, which is closely allied to the Malayan ones. They have the general characteristics and habits of the civets (q.v.) but are especially expert in tree-climbing and feed mainly upon birds.

Lin'seed, or Linseed Meal. See FLAXSEED.

Linseed Oil Industry, The. In the commercial world there are known at the present time a number of vegetable oils, which in the raw state and without the aid of chemicals are capable of absorbing the oxygen of the air to a greater or less degree, and commonly called “drying oils.” By far the most valuable to commerce, both as to usage and results obtained, is the linseed oil expressed from the seed of the plant “*Linum usitatissimum*,” the common term generally applied to this seed being “flax seed,” and probably due to the fact that early in our history the plant was commonly referred to as the “flax plant,” the object of its cultivation at that time having been principally for the flax fibre. Although the great commercial importance of linseed oil, due to the large increase of manufactured products in which it is used, has been of but comparatively recent years in this country, the seed or plant bears the hall mark of great antiquity. While there is no specific reference to linseed, it is positively known that certain drying oils had been discovered prior to the Christian Era and probably in times of remote antiquity, and, though uncertain, it would seem reasonable to assume that linseed was among them, especially as the climate of the countries where the oil seeds were found was warm and moist, and exactly suited to its growth. The first authoritative mention of linseed is made by Dioscorides, a mediæval writer on medicine, living in the time of Augustus; descriptions, however, of certain decoctions of linseed alone are given, and the resultant oil is not distinctly described. In fact, this applies to

LINSEED OIL INDUSTRY

most writers of that and later periods. They were students of natural history and medicine, and undoubtedly gave little thought to the commercial value of the oil, especially as there was at that time very little use for it. For example, Hippocrates mentions only the use of bruised linseed as a medicine of astringent properties. Pliny speaks simply of the juice of the linseed. For centuries it appears that the oil's greatest characteristic, its wonderful drying properties, was given little attention. In the second century Galen speaks only of it as being "in its nature, drying," and in the fifth, Actius, a medical writer, though distinctly describing it in connection with art, passes completely over this important point. For many years following this century, however, painting and medicine remained almost solely in the hands of the monks. Having plenty of leisure time, and guided perhaps by the expressions of former Greek writers, these monks experimented to some extent on the siccative qualities of linseed, which resulted in its limited use with other oils, principally as a preservative varnish for gilt and paintings in fresco and tempera. It was not, however, until the 12th century, when oil painting was discovered, that we may say a true appreciation of the essentially exclusive properties of linseed was felt, and from that day to this it is the only oil that has successfully satisfied all the requirements of oil painting; and, remarkable though it may seem, genius has for nearly seven hundred years sought for a substitute, either elementary or in combination, which would entirely fulfill all conditions of commerce, but without success. Whether a substitute will ever be found is extremely doubtful, and it is a well-known fact that there is no adulterant for linseed oil, inasmuch as the smallest admixture of any other oil is highly injurious to its peculiar qualities.

Manufacturing—In its early history the uses for linseed oil were few and the quantity consumed insignificant, the growth of the industry being appreciable only within the past century. In earlier years the small amount required, principally by the artists, was produced by little, if any, apparatus, and often in the studio. Later, the oil began to find more enlarged fields of usefulness, and the crudest of mechanical apparatus was devised for its manufacture. With such appliances, however, oil could be produced only at an excessive cost, and its use on a broad commercial basis was not feasible. Indeed, up to within comparatively recent years the invention and improvement of linseed oil machinery has been slow, and in fact to the United States may be attributed the greater part of the advance made in this industry in the past 100 years. The early settlers of this country, coming, as most of them did, from the flax growing countries of Europe, brought with them the primitive press which had been used by their fathers and forefathers, and upon which no improvements worth mentioning had been made. In this industry, as in many others, the United States has taken the lead, and the machinery now in use is better adapted to the purposes than in the older countries of Europe, where to-day, in fact, one may see in places the ancient oil press used by our grandfathers. The earliest method recorded for the production of linseed oil is a receipt by Theophilus, a monk writing in the 12th century,

and which becomes particularly interesting when we find that the treatment of the seed or method was almost identically the same as it is to-day. "Take linseed and dry it in a pan without water, on the fire; put it in a mortar and pound to a fine powder; then replace it in the pan, and pouring a little water on it, make it quite hot. Afterward, wrap it in a piece of new linen, place it in a press used for extracting the oil of olives, of walnuts, or of the poppy, and express it in the same manner." It will be seen from the above that the seed was treated separately four times as follows: Dried, crushed, cooked and pressed. With the exception of the drying, which is not necessary, the plan of procedure to-day is the same. During the intervening years, however, many different methods have been used as well as different kinds of machinery.

In the making of linseed oil there are two very essential steps which must be carefully watched; the first is the crushing or grinding of the seed; the second, is the cooking or "tempering" of the ground seed. In the proper manipulation of these two processes rests a crusher's ability to make a good yield of oil. Years ago the present day yield of oil would have been deemed impossible. Although the contrivances for grinding the seed were in early years as primitive as the presses with which they were used, and although many improvements have since been made, yet the grinding was fairly well done, and it seems that the light yields of oil in former years were not due so much to the grinding of the seed as to the lack of, or improper, tempering. Heat and moisture are of the greatest importance in producing the best yields; we find, in fact, that many times the ground seed or meal was pressed entirely without cooking. Oil made in this manner was called "cold pressed" oil. That such oil, however, was made through any lack of proper cooking devices or ignorance, is extremely doubtful. In years gone by little was known about the chemistry of linseed oil, but it was noticed that in the cold process the oil expressed was beautifully light in color and heavy in body; furthermore, upon boiling to a high temperature the oil did not darken but became lighter, and after mixing with the varnishes was perfectly clear and without sediment. On the contrary, oil made from the tempered meal was thinner and darker in color; on boiling at high temperatures it darkened still more, and threw down a quantity of white and greasy precipitate. Such oil of course was looked upon with suspicion; it was considered by many unfit for most uses and was never used in good varnishes. Owing to the light yield of oil in the cold process, however, the price was excessive, and for this reason much attention was devoted to the refining of the oil made by the hot process, so that it might be used in high grade goods and for particular work. For many years, however, careful men remained strongly prejudiced against hot tempering; in later years this prejudice gradually disappeared, but it was only when practical and successful processes had been invented, whereby the objectional features could be removed from the hot pressed oil. During this period, however, many thousands of gallons of the hot pressed oil were manufactured, to be used where quality was a small consideration and price of the greatest importance; in fact, an

LINSEED OIL INDUSTRY

insufficient quantity of the cold pressed oil was made to supply the demand, and Calcutta oil, which has the same properties as cold pressed oil, was imported in large quantities to make up this deficiency. In these days of sharp and bitter competition, a crusher depends almost entirely upon his yield to make his profit; consequently, all oil is made from the tempered meal, and the best equipped mills are supplied with chemical or mechanical apparatus which converts the hot pressed oil into refined oils almost equal in quality to the old time cold pressed oil. Small amounts of Calcutta oil are still imported, but the price is much higher than the domestic refined, which gives perfect satisfaction and which in the near future will undoubtedly be used to the exclusion of all others.

Probably the first attempt to manufacture linseed oil in quantities considerably in excess of that produced in the earliest times and by means of the crudest apparatus, was by the ancient screw and lever press. This was simply a modification of the old cider press and consisted of a barrel, sometimes of cast iron, perforated to give a free outlet to the oil, and fitted with a plunger which, when actuated by the screw, descended into the open barrel upon the mass of meal contained therein, and by means of slow pressure thus exerted expressed a reasonable amount of oil. This press was worked by a hand lever placed through an eye at the head of the screw, like a bar in a capstan. Little oil was secured, however, in comparison with presses actuated by machinery, where the pressure is many times greater than can possibly be secured by hand. On this account considerable oil remained in the dry residue known as oil cake; these weighed about 25 pounds each and were about 18 inches in diameter by 8 inches thick, resembling a cheese in shape and thus giving to it the name of "Cheese Box" press. The capacity of this press was small indeed, amounting to less than one barrel of oil a day. The date cannot be definitely stated when the screw and lever press was first used, although linseed oil was undoubtedly first made by it in this country. It was retained in use as late as 1848. Many years prior to that date, however, the improved Dutch mill or wedge press had come into vogue. These mills were imported early in our history from Holland, where in some places they may be still seen in actual use, and were at that time considered a great improvement over the old screw and lever presses. The wedge press as it was introduced to America consisted of a very heavy rectangular frame work of oak or iron, placed horizontally on its base. The ground seed was shoveled by hand into woolen bags and these were placed in the press so as to hang vertically between hinged partitions, consisting of wooden plates. The capacity of the press was about nine or ten of these bags, and giving a daily pressing of not over 15 to 20 bushels. The cake manufactured in this press weighed from 8 to 10 pounds each, after the raw edges had been trimmed. The pressure requisite for the expression of the oil was obtained by driving wooden wedges between the plates by means of sledges driven by wind or water power.

It is impossible to state at just what time the wedge press was discarded for the horizontal hydraulic press, the next step in the advance-

ment of the industry and undoubtedly the most important. Linseed oil, however, was made by this process as late as 1853. In 1796 the first hydraulic press was built. This brought about great changes in many industries as well as in the manufacture of linseed oil. The first presses were indeed very small affairs in comparison with those now in use, but their invention was an epoch maker in the linseed oil industry. The earliest type used was similar to the old screw and lever press in shape, and of the cheese box variety. It is doubtful, however, in the absence of authentic records, that this variety was used in this country for linseed. Probably the first hydraulic presses used in the United States for linseed oil were of the horizontal type, having been installed in a New York mill shortly after the war of 1812. In these presses the plates were of iron instead of wood, and movable; the ground seed was shoveled into the woolen bags as before, but flattened by the hand of the workman and placed in mats of horsehair, which were folded in book form. After placing in the press vertically, one at a time, the iron plates were moved up against each bag, when the ram of the hydraulic cylinder moving horizontally compressed the eight or nine cakes contained in the press, the oil running into a trough or pan beneath. Very simple hydraulic pumps were used at that time to generate the pressure; the yield of oil, however, was very much increased by this method, it being practically impossible to secure a sufficiently high and steady pressure by the old wedge and screw process. The horizontal press, however, though an improvement over these methods, had its disadvantages. In 1851 the first patents for vertical hydraulic presses for linseed oil were granted. The capacity was not increased over the horizontal type at this time, the press holding only 6 to 10 cakes. The clumsy and unwieldy manner of packing the meal in the bags and filling the presses, however, was done away with. What is known as "boxes" were used, the ground seed being molded into soft cakes, packed in wrappers and placed in the press, one above the other, the boxes acting as shelves. A large saving was made here in labor and time, necessarily resulting in considerable increase of capacity and consequent reduction in the cost. With the improvements in the manner of pressing the seed came improvements in grinding or crushing. For many years undoubtedly the mortar and pestle of Theophilus was used on some basis; this, however, was very crude, and took an unnecessary amount of labor. Linseed was crushed first in this country by rolling through a mill worked by hand; the rollers in this mill consisted of one large and one small, the seed being passed through once or twice, according to the views of the crusher. This mill in the earliest time was probably used with the screw and lever press. The earliest method for reducing the linseed to meal by machinery was that used in connection with the Dutch mill or wedge press, and was called the "Tamper" mill. This was a mortar and pestle on a large scale. The mortars were of heavy cast iron, the bottom flat on the inside and holding a small amount of flax seed; the pestle was an iron-shod log, standing vertically in a frame, the foot resting on the bottom of the mortar; these logs, weighing from 150 to 200 pounds each, were raised, by means of

LINSEED OIL INDUSTRY

cams on a horizontal log, by water or wind power, and falling of their own weight exerted a crushing or grinding force upon the seed. The tampers, as they were called, numbered one or more in the set, according to the size of the mill. As in the case of the screw and wedge press, however, this method was found entirely inadequate to the needs of the oil mill. The capacity of a mill was necessarily cut down very much by such a slow process, and rolls run by machinery were resorted to; these were of different design from the old hand rolls, and were designated in the trade as "cracker" rolls, for the reason that they cracked or opened the seeds. These rolls were arranged in pairs only and varied in size from 12 to 18 inches in diameter and 7 to 18 long, according to the views of the manufacturer. After being bruised in these rolls, the seed was placed in an edge-runner or chaser, also known as a "Muller" stone. This consisted of a circular trench of iron, several feet in diameter, placed horizontally on a firm foundation. Running around this, like a wagon wheel in a rut, were two ponderous iron shod wheels, 5 to 6 feet in diameter with steel tires 10 to 16 inches wide. These were sometimes made of stone and set opposite one another on a shaft and weighed about 7,000 pounds each. Around and around these wheels revolved, chasing one another until the meal was finely crushed and rolled, when water was added until the meal acquired the consistency of putty, or what was termed as "dobby." It was then mixed or "mulled" for some 10 or 15 minutes and then tempered. These Muller stones proved very satisfactory as to results, but were clumsy and took a great deal of power; furthermore, the expense of two grindings was unnecessary. Nevertheless, no change was made for many years.

The tempering or cooking of the crushed seed having such an important bearing on the yield of oil, has also suffered many changes. In the earliest times many different devices of the crudest workmanship were used, often no more nor less than large cooking utensils; there was also considerable variation in the temperature used, from cold to hot, according to the manufacturer. Often the spontaneous heat of the crushing was considered sufficient. In the tamper of the Dutch mill water was played on the meal in the mortar, when vapors began to arise, in order to keep it from getting too hot and thus spoiling the oil. No further tempering was considered necessary. Later, however, and notably in connection with the Muller stones and wedge press, regular cookers began to be used; these were heavy sheet iron drums or tanks, slowly revolving over a charcoal fire until the proper temperature was attained. With the advent of the hydraulic press, however, improvements were made in cooking devices and stationary heaters began to be used in which the meal was cooked by steam. Up to the year 1856, and as related, the cooked meal was placed in the bags by hand; at this date, however, a device was patented to form the cooked meal into soft cakes or molds preparatory to placing them into the cloth or wrapper which was to take the place of the bags originally used. This was considered a great boon, saving as it did, the laborious process of handling and molding the meal by hand to fit the press; though somewhat clumsy at that time,

the "molder" or "former" has been much improved. Where in former years the molder was run by power from the shaft, now hydraulic pressure is utilized, and the "former" is in reality a miniature press, consisting of a square mold or box into which a plunger presses the required amount of meal. Very light pressure is sufficient, and it is so arranged that the cooked meal will not be compressed beyond the point where the oil is separated.

The tempering, crushing and pressing of linseed was carried on, with a few exceptions, substantially as related up to the year 1878, when the most lasting improvement to oil machinery was made, and which introduced practically the system in use at the present time; namely, the "Lawther" process. Greater economy was immediately secured and larger yields of oil. The old Muller stones and cracker rolls gave way to the stack of "four or five high" chilled iron rolls, by means of which the seed was bruised three or four times in one process. Apparatus for controlling and regulating the high pressure was introduced; kettles or cookers were steam jacketed and had larger heating area, and steam was fed into the meal to moisten as well as heat it. The plate press had also been given the preference over the box press, which was clumsy. Although the very best mills to-day have some improvements over the original Lawther process, they make rather toward greater economy than increase of yield. The modus operandi in the largest and most complete mill to-day is as follows: The flax seed is first thoroughly cleaned by separators and dust collectors until the original dirt, amounting to 10 or 20 per cent, has been reduced to less than one per cent, and which is considered as clean as it is practical to make it. This seed is now passed through the rolls, there being about one set of five rolls high to every three presses. The ground seed falling from these rolls is led by screw conveyors into the steam jacketed cookers of large capacity and holding a considerable quantity, where it is tempered. This consists of heating the ground seed to a temperature of from 120° to 180° F., according to the quality of the seed used, and moistened with live steam, all the time being kept in constant motion to prevent burning. When the temper is considered perfect a batch is made. This consists of drawing off the cooked meal on to the formers and molding the cake; these molders are the latest design and are very rapid in action. A piece of cloth somewhat wider than the molded cake is placed so that the tempered meal may be drawn out onto it. This cloth or wrapper, as it is called, is a substitute for the horse hair cloth and woolen bags of former days, but now made of pure camel's hair to stand the high heat and enormous pressure. By a single motion the former is now closed and immediately reopened, when the ends of the cloth protruding are wrapped around the soft cake and it is placed in the press. The batch consists of making 20 of these cakes, which fills one press. The pressure is now turned on by an automatic valve or change cock, which slowly increases the pressure up to about 4,000 pounds to the square inch. This enormous pressure is generated by very powerful hydraulic pumps, connected to what is known as the accumulator system. The accumulators are for two purposes; first, to act similar to a

LINSEED OIL INDUSTRY

safety valve on a boiler, preventing the pressure from exceeding the limit; secondly, keeping the pressure at a steady level throughout the time the seed is in the press, and preventing the pressure from decreasing one pound. Before the adaptation of the accumulator and change cock, the oil was pumped directly into the press, causing an unequal flow and consequent reduction in the yield of oil. Six presses are generally grouped, one being emptied and refilled every ten minutes, the six thus completing one hour in time and allowing each press in the group to drain every 50 minutes. In some mills seven batches are made instead of six, and the weight of the cake is also increased from 11 and 12 to 14 pounds. This is done in order to increase the capacity of the mill, but generally at a sacrifice in yield of oil. As each batch is removed from the press, the camel's hair cloth wrapper is stripped off, the rough edges of the cake trimmed automatically, and the cake piled up in the cake house, where it is allowed to cure or dry for at least 48 hours. The raw oil, after having been run from the settling troughs at the back of the presses, is carefully filtered and placed in tanks ready for barreling.

The Oil and Its Uses.—Linseed oil as manufactured may be classified under three headings: raw, boiled and refined. Raw linseed oil is the term applied to oil as it comes from the press in its original state. The principal consumer of raw linseed oil is the paint grinder; as it was used as a vehicle for paint hundreds of years ago, so it is used now. Every year millions of gallons are spread on our houses and public buildings in the form of mixed paints, one concern alone using over 1,500,000 gallons yearly. Every 100 pounds of white lead contains at least $7\frac{1}{2}$ gallons. Boiled linseed oil is, as the name denotes, raw oil boiled over a fire, chemicals being added, the object being to increase its drying properties. Many formulae are used by the different crushers for making boiled oil, the oldest and most reliable, however, containing principally red lead and black oxide of manganese, the addition of these metals to the heated oil stimulating the linoline and increasing its affinity for oxygen. The uses for boiled oil are many and varied, but it is principally used as the drying oil in paints. The refined or varnish oils are many, and there is the greatest rivalry to-day among oil manufacturers as to the qualities of their respective varnish oils. Hundreds of thousands of gallons of these oils are used every year. While the different gums used in the manufacture of varnishes are the basis or foundation, some variety of refined oil is the most important component of the varnish. As stated before, raw linseed oil has certain component parts which must be removed; there are many ways of doing this. Descriptions, however, of these methods will not be attempted, as they pertain more particularly to the chemistry of linseed oil and not to its manufacture. The reliable varnish oils are few and are furnished only by the largest manufacturers. Linseed oil in some form plays a very prominent part in the manufacture of linoleum and oil cloths also. Varnish oils are used in the manufacture of patent leather, for shoes and other purposes, carriage tops, and all kinds of dressed leathers are finished with linseed oil. The oil clothing worn by sailors and fishermen is soaked with it. It

appears by the thousands of gallons before our eyes in the printers' ink on newspapers, and smaller quantities are used in the manufacture of oil silks. Strange to say, linseed oil has no value as an edible oil, or as an illuminant or lubricant. In a few instances we find linseed oil used fresh from the press as a cooking oil and even as a substitute for butter, but mostly by foreigners, notably Russians or Poles; it is needless to say, however, that the consumption in this way is most insignificant. As an illuminant it is useless, burning only at high temperatures with much smoke and giving a poor light. As a lubricant it has no value, although sometimes used as an adulterant, but its drying qualities are obviously the reverse of those required of a good lubricating oil. While not very large in comparison with other industries, the consumption of linseed oil in the last few years as compared to former years has increased very rapidly, and at the present time the above industries consume annually an amount computed at nearly 62,000,000 gallons. The price of linseed oil is of course governed by the cost of manufacture and principally by the price of seed and cake. Large fluctuations in the price of a commodity are generally very injurious to the trade in such commodities. While the fluctuations in linseed oil have been very large at times, the growth of the industry has been such that no great apparent injury has been done. Probably the highest price ever obtained for domestic raw oil was \$2.03 per gallon in 1867, the price having risen gradually from \$1.00 per gallon in 1861. These prices were, of course, war prices, and after 1867 steadily declined, ranging from 60 to 70 cents as high, and 40 to 50 cents as low. It is a remarkable fact that in these days of great production, manipulation has succeeded in placing the price as high as 82 cents in 1901, the highest since 1870. Owing to the somewhat limited and narrow market for domestic linseed, such manipulation is often brought to bear, and it is the earnest desire of every crusher that this may be eliminated to some extent in the future. The lowest price at which linseed oil has ever sold in its history was in 1867, when actual sales were made on the basis of 24 cents per gallon in wooden barrels. This of course was due largely to the financial panic together with large crops at that time and prices rapidly recovered to a normal basis. The greatest fluctuations experienced in earlier years was in 1867, when oil went from \$1.00 per gallon to \$2.03, and in later years, in 1901, when it went from 50 to 82 cents per gallon. Linseed oil has always been subject to great fluctuations, and it will be seen by averaging that from 1876 the annual fluctuation has been about $14\frac{1}{2}$ cents per gallon, the smallest fluctuation known being in 1883, when there was only 3 cents difference in price at any time during the year.

The Cake and Its Uses.—While really a by-product, the manufacture and sale of the cake is equal in importance to the sale of the oil, and although netting a smaller price per pound, the value has a very great influence on the course of oil prices and the policy of the business as a unit. Practically the only use for cake is as a food for live stock, principally cattle, for fattening and for results in the dairy. The actual protein in cake is about 36 per cent, of which about 85 per cent is digestible and the nutritive

LINSEED OIL INDUSTRY

value is consequently several times that of hay, while the fat varies from 4 per cent to 8 per cent, according to the crusher. Although used extensively abroad, it is a singular fact that our farmers in the United States have little, if any, appreciation of its value. Our own country should be the largest consumer of this most valuable by-product; actual figures, however, show that only about 20 per cent is retained for home consumption. The first cost is somewhat greater than for other food stuffs, and our farmers as a general rule lack the knowledge of its value, which comes only by experiment and valuable experience. The manurial value alone of linseed oil cake has been estimated at over \$16.00 per ton, whereas the first cost is only from \$18.00 to \$25.00 per ton. Our farmers, it is true, are waking up to its value and more is being used in this country every year, but the bulk of our output is marketed in two very small countries, Holland and Belgium. It is impossible to ascertain the exact quantities of linseed cake exported in the early years of the industry, as all oil cake and oil cake meals were classified under one head. It is, however, fairly safe to assume that by far the larger part of the output each year in the proportion of about 38 to 40 pounds of cake per bushel of seed crushed was sent out of the country; this from the fact that only in recent years has our farmer become educated to its use.

While the two little countries of Holland and Belgium take at the present time about 67 per cent of the cake consumed in all the other countries of Europe, this demand has been of but comparatively recent years. The United Kingdom in years gone by was considered the only market, and Holland and Belgium used only small quantities. For instance, in 1895 only 20,000 tons were shipped to Belgium and 9,000 tons to Holland, whereas in 1896, 115,000 tons were consumed in the United Kingdom. The United Kingdom, however, has reduced her demand ever since that time, while Holland and Belgium have taken rapid steps. From 20,000 tons in 1895, Belgium has increased to 100,000 tons in 1902, and Holland from 9,000 tons to 86,000 tons, while the United Kingdom dropped to about 50,000 tons. As stated, the exportation of cake has grown with the industry and the proportion of export remains practically the same, with the exception that each year a little more is retained for home consumption. The total exports in 1895 were about 120,000 tons, and in 1902 about 290,000 tons. A glance at the figures will show that of the total 290,000 tons the three countries above mentioned consumed 242,000 tons, the balance being divided largely between France and Germany with 18,000 tons each, Canada and West Indies 5,000 each, and Norway, Sweden and Denmark insignificant amounts. It is quite remarkable that so much of our cake finds its way to foreign markets, as the competition is severe, Russia, Germany and England together crushing many millions of bushels of seed annually. In England at least, however, the explanation is simple; more attention is paid to the richness in oil of the cake than in America. The oil is the most valuable product; consequently, with characteristic aggressiveness the Americans proceed to express all of it, or nearly all, leaving only about 6 per cent to 8 per cent in the cake. The result is a

much harder cake with considerably less oil in than in that made by our English cousins. This accounts in a great measure for the decrease in the United Kingdom consumption of our cake, and also owing to larger importation of the cheaper cottonseed meal which contains a greater percentage of oil. For some reason, however, the dry, hard American cake seems to be just the correct thing for growing, fattening and feeding cattle for the dairy. The quiet Dutchman prefers our cake above all others, and one need only to look at the figures to prove this statement. It is a very peculiar thing that the use of oil cake is not as general as it seems it should be. Like the American farmer, the Dane for instance will hardly touch it. He claims it spoils the flavor of the milk when fed for this purpose, and although good for fattening is too high priced as compared to cottonseed meal. How it is that Denmark holds the opposite opinion from Holland and Belgium is difficult to explain; it would seem, however, that the immense quantity used by the above mentioned countries, and the world-wide reputation of their dairy products, should conclusively settle the question, and it is altogether probable that on the basis of digestive economy, linseed oil cake is the best food of its kind on the market to-day.

Growth of the Industry.—As stated before, the early settlers brought with them the knowledge of making linseed oil. As the uses then were but limited, very little attention was given to the oil; the flax plant was grown for the flax and not for the seed and oil. In 1719 the spinning wheel was first introduced in New Hampshire by the Protestant Irish who settled there, and flax was grown more abundantly. The seed was for the most part exported, a few thousand bushels only being necessary to fill the home oil wants. The first impetus to the growth of flax for linen fabrics and consequent increase in seed and oil was given in 1722, when bounties for its growth were granted. The increase was immediate, and the plan worked so well that the bounties were continued, and in fact increased, until in 1751 we find it reported that sixty wagon loads of seed were exported at Baltimore. In 1752 a further increase was noted, 10,000 hogsheads or 70,000 bushels of seed being exported from Philadelphia. Twenty years later, 110,000 bushels were sold to the foreigner, and in 1791 292,000 bushels, or upwards of one half of the total crop of the United States in 1860, which was 567,000 bushels. Some idea of the rapid growth after the Revolution will be gained from the fact that in 1791 only 450 gallons were exported, while in 1795 nearly 50,000 gallons were sent abroad, an amount which was not again equaled until sixty years later. In 1792 the invention of the cotton gin placed a severe check on the growth of flax for the fibre, cheapening as it did cotton and cotton fabric. Undoubtedly at this time closer attention was paid to the flax seed for its oil bearing seed; the business was a profitable one, as had been shown by the small export business done. From 1795 the export steadily decreased, showing ever increasing home consumption, and in fact considerable quantities were now being imported. From about 80,000 gallons in 1825, they increased to 3,200,000 gallons in 1867. Short crops and high prices during the war of 1861-5 undoubtedly affected the im-

LINSEED OIL INDUSTRY

portation of oil to some extent, but the indication is that there was a heavy demand for the oil which had to be filled. As the case in many other industries, the protective tariffs had a great effect on the production of linseed oil. In 1861 a duty of 16 cents per bushel was placed on flax seed, and 23 cents per gallon on linseed oil. Owing to the fact that very short crops of seed had been grown during the War of the Rebellion, and to the fact that business started up with a boom soon after, large quantities of oil were imported regardless of the duty,—1,150,000 gallons in 1866 and 3,200,000 gallons in 1867. Immediately after this, however, the imports dropped to an insignificant quantity, and have continued so to this day, a certain quantity of Calcutta oil only being imported each year at high prices, for special uses, it being a well known fact that the finest oil in the world is made from East Indian seed. It should also be noted that from 1861 to 1892 practically no seed was exported; it is also interesting to note that though in 1871 a duty of 20 cents per bushel, and in 1897 of 25 cents per bushel was levied, this country continued to import seed in respectable quantities, having reached as high as 4,166,000 bushels in 1895. The conclusion is obvious. The tariff on oil effectively eliminated the foreign competition; the crops of seed grown could not supply the demand; the price of seed goes up and the farmer is encouraged to plant it, while the duty on the seed for import holds that quantity down to an amount necessary to fill our shortages only. By glancing at our statistics, we are surprised to note that although a high duty has been levied on incoming flax, the growth of the industry has been such that until very recent years we have been obliged to call on the foreigner for some of our supplies. In 1839 the first cargo of flax was imported, and from 1854 to 1891 we have been obliged to call for, from one to three million bushels annually, with the exception of 1882 and 1883. In 1895 we needed 4,160,000 bushels to fill our consumptive needs. It is useless to make any estimate, which would approach with any degree of accuracy, the amount of flax seed grown in this country from year to year; this is due to the fact that the figures on record are sometimes estimated in one way and sometimes in another. It will be sufficient to say, however, that from 1880, when the crop grown in this country aggregated some 7,000,000 bushels, we have increased to at least 30,000,000 bushels in 1903. In 1902 the crop grown was estimated at about 25,000,000 bushels; prior to that time, however, and as far back as 1880, the average was about 10,000,000 bushels each year. By taking an average of the available crop used for crushing, after adding the imports and deducting the exports, we find that the average consumption amounted to eight to ten million bushels of seed up to about the year 1892. From that time the statistics seem to show a steady increase in the consumption, until at the present time it would appear that from 22,000,000 to 24,000,000 bushels are crushed, or in the neighborhood of one and one-half million barrels of oil.

Price of Seed.—While at times the fluctuations of seed prices has been caused by heavy speculation and manipulation, the law of supply and demand has generally fixed the value. The earliest quotations of which we have an authen-

tic record are for the year 1855; at that time Cincinnati was the principal centre for the sale of the seed. From about 1870 Chicago became the great market, its location being more central and better adapted for its marketing. Ten years later, however, Chicago lost its prestige, and Duluth, the wonderful city of the Northwest, has become practically the only market, located as it is at the head of the Great Lakes, which gives splendid shipping facilities for the large crop grown in the large states of North and South Dakota and Minnesota. The highest price obtained for linseed in modern times was in 1862, when sales were made on a basis of \$3.25 per bushel. From 1862 to 1874 seed never sold under \$2.00 per bushel but averaged about \$2.50; after 1874, however, prices steadily declined until 1886, when \$1.03 was reached. The lowest price ever obtained was in 1897, when seed went to about 63 cents. The greatest fluctuation was in 1862, seed going from \$1.25 to \$3.25, or a difference of \$2.00. Flax seed has never fluctuated less than four or five cents a year, and this condition has prevailed but seldom. In speaking of the great increase in the crops of seed grown, it is interesting to note in a general way its peculiar migratory nature. In earlier times, almost all the seed was grown in the Eastern States; large amounts were grown in New York, whereas now scarcely any is grown there. Ohio long held a good share of the crop; from Ohio it traveled to Indiana and Illinois; then Kansas, and from there to Minnesota and Dakota, and finally, in the last few years, almost the entire crop has been grown in the great States of North and South Dakota, Minnesota, and Manitoba. The historical records furnish us with very meagre data as regards the number of mills in operation at different periods. In 1810, the census tells us there were 383 mills in 14 States, 171 in Pennsylvania alone. These mills of course were very small affairs, but the number is conclusive of the healthy growth and the large interest taken in this industry. These mills made 770,000 gallons of oil, valued at about \$900,000. No better index of the growth of the industry can be had than a comparison of the following figures: In 1860 there were 94 mills, turning out nearly \$6,000,000 worth of oil and cake; in 1870 the number of mills was reduced to 85, but the value of the products had increased to \$9,000,000 worth of oil and cake, and in 1880, 81 mills produced \$15,400,000 worth of products. The number of mills was still further reduced in 1890 to 62, making \$23,500,000 worth of oil and cake, and in 1900 it is estimated that 48 mills were producing the splendid total of nearly \$30,000,000. The steady decrease in the number of plants in operation is due of course to the weeding out of plants with poor and old fashioned machinery and those unable to work on the lowest basis of cost manufacture for various reasons. There are at the present time not over 30 mills in actual operation, and combining in the aggregate some 730 presses. In measuring capacity, the unit is generally a hydraulic press. Each press of standard size, containing 20 cakes, is capable of handling in the best managed mills about 40,000 bushels annually, if run 300 days in the year. As in many other industries to-day, there are two controlling interests concerned in the production of linseed oil, the combine and the independents. Between these

LINSEITE — LINTON

two elements the annual crop of flax seed is crushed and placed on the market. The number of presses computed for the combine is about 360. The independents number about 410 presses, out of which number the three largest independents operate 236 presses, or about 60 per cent. A comparatively small number only of the above presses, however, are equipped with the full number of 20 plates; every mill, therefore, if run full could not crush the maximum of 40,000 bushels per press. Many mills have only 16 plates, and for the purpose of approximating the correct figures it will be safe to estimate that fully 60 per cent of the total number of presses operated have a capacity 80 per cent of the standard size. It will be seen, therefore, by computation, that on this basis the actual crushing capacity of all the presses in actual condition to run is over 27,000,000 bushels. As some few mills run a larger quantity by operating seven batches or more and running heavier cake, it is probable the actual capacity of the machinery in use is nearly 30,000,000 bushels, or from 6,000,000 to 8,000,000 bushels in excess of the amount required. Necessarily, such condition of affairs causes many of the mills to run only part of the year and some of them to shut down entirely. Not over ten years ago a mill containing 12 presses was considered a good size, and 24 presses was considered very large; in fact, there are very few mills in operation to-day that number more than the latter figure. The largest mill in the world is located in Buffalo, N. Y., and operating steadily the large number of 138 presses, having a capacity of 6,000,000 bushels of flaxseed, and turning out about 15,000,000 gallons of oil annually. The four principal crushing points, as shown by the number of mills and amount of crushing capacity, are Buffalo, Chicago, Minneapolis and New York, the number of presses in operation in Buffalo being 203, with capacity of over 8,000,000 bushels of seed. Minneapolis is second with about 120; Chicago next with 113, and New York fourth with 108, or a total of 544 out of the entire number of 770 presses, the balance being scattered over the country at various points. See also FLAXSEED; OIL.

SPENCER KELLOGG,
Of Spencer Kellogg, Buffalo, N. Y.

Linsey, the name of an English country-made fabric of linen warp and worsted filling.

Linsey-woolsey, a mixed fabric made of linen and wool.

Linsley, James Harvey, American naturalist: b. Northford, Conn., 5 May 1787; d. Stratford, Conn., 26 Dec. 1843. He was graduated from Yale College in 1817, and became a Baptist clergyman, but on account of increasing ill-health resigned from the pulpit and devoted himself to the study of natural history. Many catalogues of mammalia and birds from his pen may be found in the 'American Journal of Science.'

Linsley, Joel Harvey, American clergyman: b. Cornwall, Vt., 15 July 1790; d. Greenwich, Conn., 22 March 1868. He was graduated from Middlebury College in 1811, and was tutor there for three years; afterward studied law, but in 1822 was licensed as a Congregational clergyman and went to South Carolina as a

missionary. During the years 1824-32 he was pastor of a church in Hartford, Conn., and was at Park Street church, Boston, 1832-5. In the latter year he was elected president of Marietta College, Ohio, which post he held 10 years, raising a considerable fund for the institution.

Linstock, a gunner's forked staff to hold a match of lint dipped in saltpeter.

Lint, in surgery, the scrapings or ravelings of fine linen, made into a sort of cloth, and used by surgeons in dressing wounds. It is made into various forms, which have different names, according to the difference of the figures. Lint made up in an oval or orbicular form is called a plect; if in a cylindrical form, or in shape of a date or olive-stone, it is called a dossier. The advantages of this material are very great, owing to its softness of texture, the ease with which it can be folded or rolled into any shape required, its capacity to absorb discharges, and its cheapness, on account of which it may be thrown away when once used. For modern surgery, it is rendered antiseptic by steeping in carbolic acid, perchloride of mercury solution, etc., and subsequent drying.

Lint-doctor, a sharp-edged ruler on the delivery side of the calico-printing cylinder, to detain any lint or fibres which may come off the cotton cloth.

Lin'tel, in architecture, a horizontal timber or stone over a door, window, or other opening, to discharge the superincumbent weight.

Lin, Richard, American journalist: b. Libertytown, Md., 30 March 1859. He was educated in Baltimore schools and at Liberty Academy. From 1877 to 1880 he served as an observer in the United States Weather Bureau, and since 1883 has been engaged in writing for newspapers and magazines, to which he has contributed short stories, etc. He has also published 'Rocky Mountain Tales' (1892); 'Boer and Britisher in South Africa' (1900); 'Best Recitations' (1902); and 'Educational Encyclopedia of Common Things' (1903).

Lin'ton, Eliza Lynn, English novelist: b. Keswick, Cumberland, 10 Feb. 1822; d. London 14 July 1898. In 1858 she married William James Linton (q.v.), but they separated in 1867, though continuing to retain friendly relations until his death. She was connected with the press for nearly all of her literary career, writing for the 'Saturday Review' the celebrated 'Girl of the Period' papers. She sometimes dipped her pen in acid, but in private she was warm-hearted and self-sacrificing. Among her numerous works are: 'The World Well Lost'; 'The One Too Many'; 'In Haste and at Leisure'; 'The Girl of the Period'; etc. Her best novels are: 'The True History of Joshua Davidson: Christian and Communist' (1872); and 'Autobiography of Christopher Kirkland.'

Linton, Sir James Dromgoole, English painter: b. London 26 Dec. 1840. He was educated at Cleveland House, Barnes. He afterward studied art, and has done much to promote the interests of the English school of water-color painting. He was elected a member of Institute of Water-color Painters (1867). When it was reorganized, its title being henceforth the Royal Institute of Painters in Water-colors, and its exhibitions being thrown open to everybody, not confined, as hitherto, to mem-

LINTON — LION

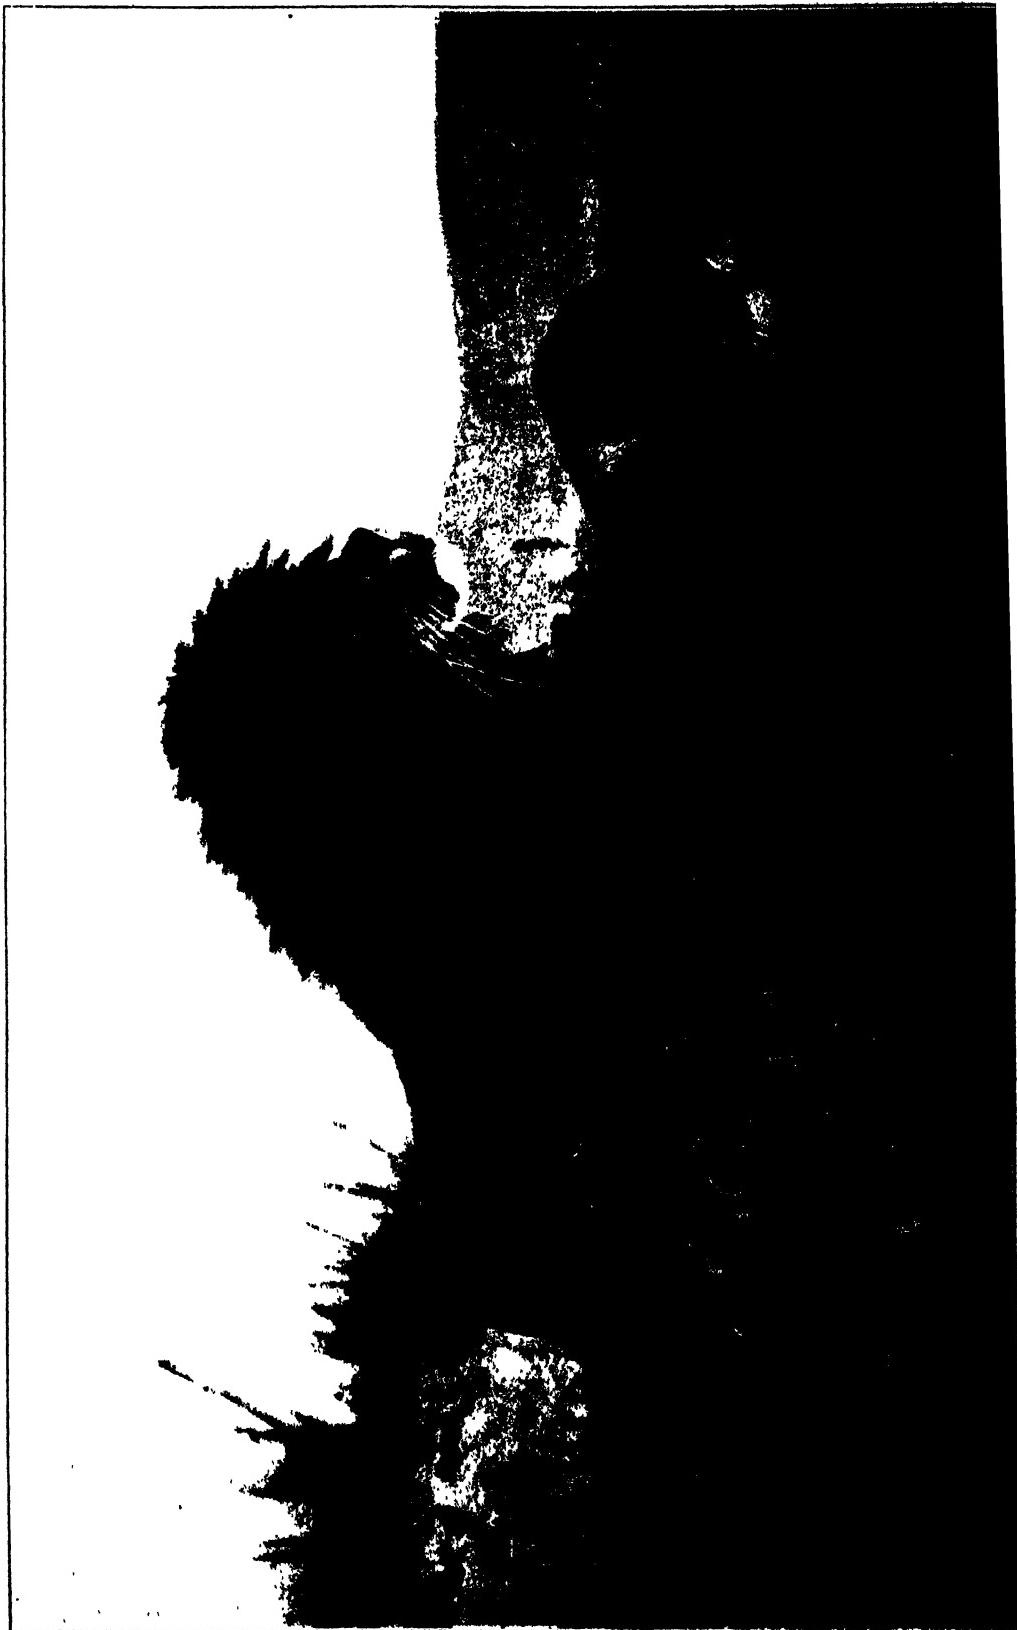

bers, he was chosen president (1884). In the following year he was knighted. His pictures in oil include the "Marriage of the Duke of Albany" painted in 1885, and a series of panels illustrating 16th century history for a private mansion at Nottingham.

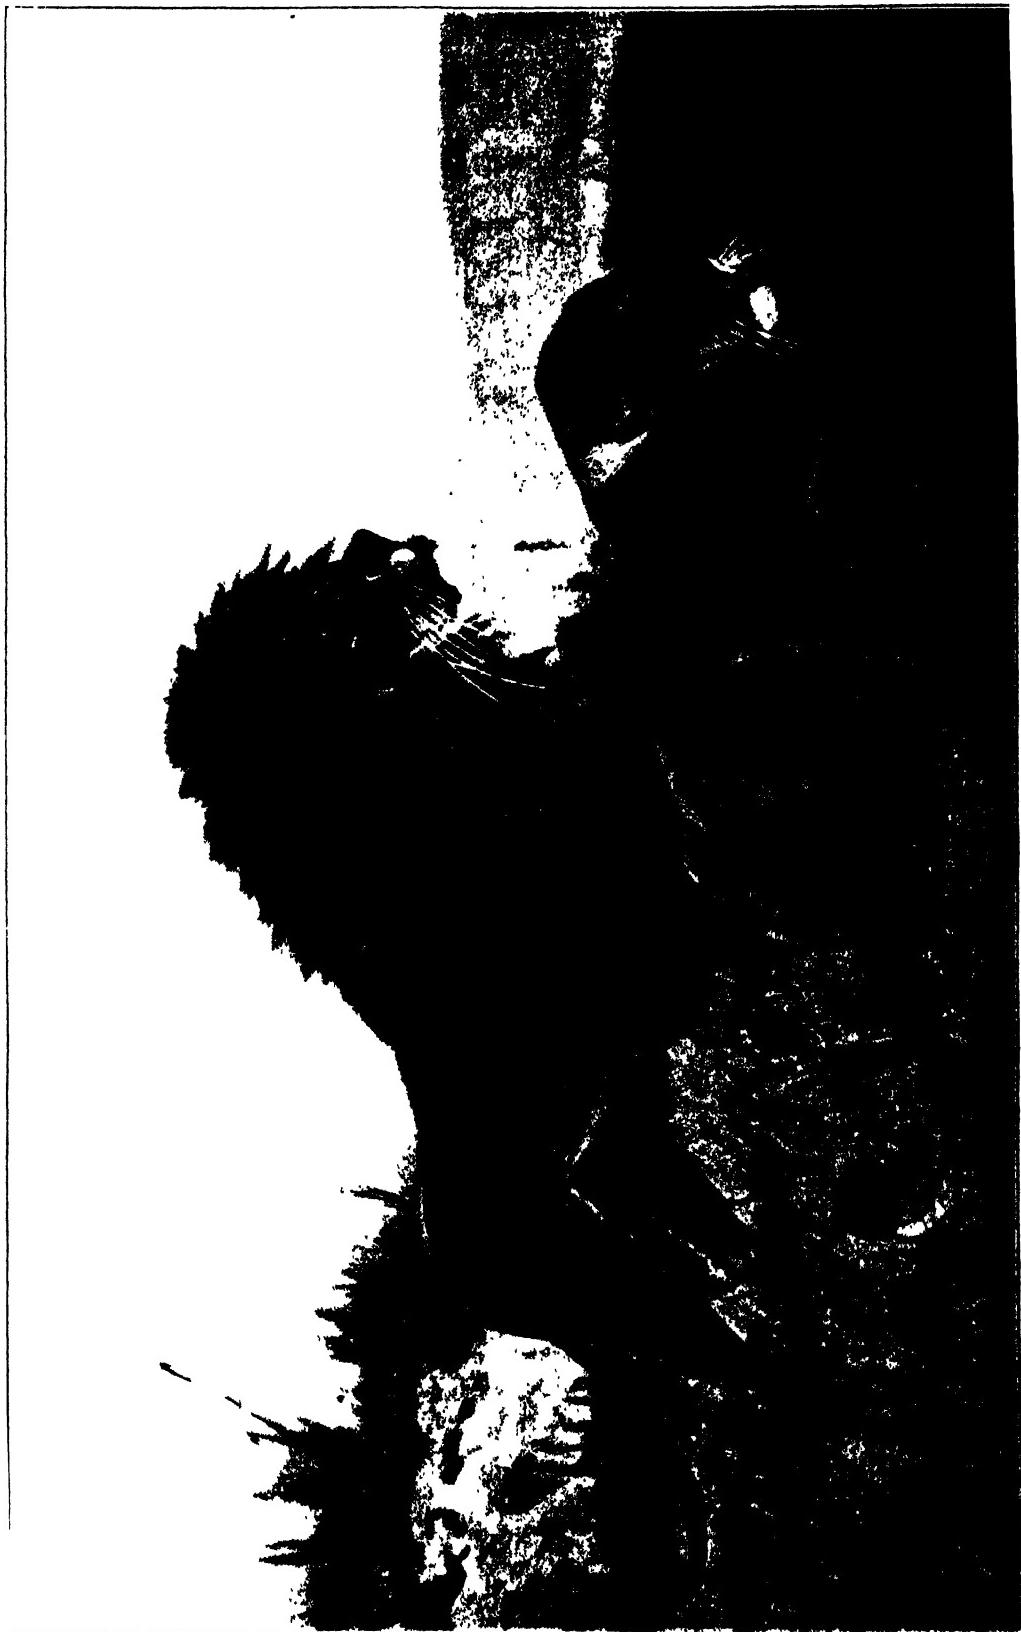

Linton, William James, Anglo-American wood engraver and author: b. London 1812; d. near New Haven, Conn., 29 Dec. 1897. As a wood engraver he took very high rank, and some of his finest work may be found in the pages of the "Illustrated London News," to which he frequently contributed from its commencement till he came to the United States in 1867. As an author, in which capacity he was more widely known than as an engraver, the zealous Chartism of his youth tinged much of his earlier work. Among his works may be cited: "The Plain of Freedom" (1852); "Claribel and other Poems" (1865); "The English Republic"; "Some Practical Hints on Wood Engraving" (1879); "Life of Thomas Paine" (1879); "A Manual of Wood Engraving" (1884); "Poems and Translations" (1889); and "The Masters of Wood Engraving" (1890).

Linz, lints, Austria, the capital of Upper Austria, on the Danube, 98 miles west of Vienna. It is defended by detached forts extending over a circuit of 9 miles, and has an old cathedral, a new cathedral, provincial parliament house, castle, town-house, bishop's palace, etc. The manufactures include woolen, linen, silk, and cotton goods, machinery and hardware, and there is an extensive trade on the Danube. Pop. (1900) 58,788.

Lion, the largest and most celebrated of the cat tribe, forming the widespread species *Felis leo*. The outward form and appearance of the lion are familiar. The apparently excessive size of the head, due chiefly to the great mane which covers the head, neck and shoulders of the males; the uniform, unmarked, tawny color of the skin; the great development of horny papillæ upon the rasp-like tongue; the growth of long hair on the elbows and along the middle line of the belly, and the tuft at the extremity of the tail (hiding a horny spine) are distinctive external characters. The length of the lion from nose to tip of tail, rarely, if ever, exceeds 10 feet, and that of the lioness 9 feet, of which the tail forms a third. The older books separated a supposed species of maneless lion, especially one in India designated the maneless lion of Gujarat; but the development of the mane varies greatly, some lions in all regions having this feature much more abundant than others, and in all cases it is a product of age, appearing fully only when the animal has reached full maturity at the age of five to seven years, so that no distinction of this kind is valid; nor can any be made upon color, the mane in certain specimens being very much darker than in others without regard to locality, dark and amply maned and scantily maned individuals belonging sometimes to the same litter. The period of gestation in the lions is five months. Only one brood is produced annually, and from two to four young are produced at a birth. The mother nourishes the whelps for about a year; their size at birth being about that of a pug-dog. In their young state the whelps may be marked with various markings; brown bands upon a tawny body color and a stripe along the

spine, being most frequently observed. As they grow older, however, the markings disappear, and the uniform tawny hue of the adult is reached. The probable limit of age of the lion has been differently stated by different writers. Buffon fixed it at twenty-two years. But a lion which died in the Tower of London in 1760, had lived in captivity above seventy years. The habits of lions have been observed and described by more writers than in the case, perhaps, of any other animal; and they are known to vary constantly with circumstances, locality and the kind of prey available. In general this heavy animal, which is entirely unable to climb into trees, and frequents open rather than forested regions, gains its food by stealth and power rather than by agility and speed. Lions often go abroad by day, wandering and hunting widely; but are chiefly active at night. Then this great cat goes to some accustomed lurking place near a spring or by the side of a river, where, concealed among the brushwood, he lies in wait for the animals coming to drink. A single powerful leap generally lands him upon his prey which is crushed down by the weight of the attack and mauled and bitten about the head until the neck is broken by a wrench, or the veins and arteries are torn open. If no rivals are near, and the animal is very hungry, the prey may be devoured on the spot to the extent required to satisfy appetite; and then, after drinking copiously, the beast will usually go away to his lair, leaving the remains for his family, if they have come near (as often happens), or to hyenas and jackals. In most cases, however, the lion, like other great cats, chooses to take his quarry to some retired spot where he may feed upon it unobserved; and amazing stories are told, with apparent truth, of the strength displayed in carrying or dragging the carcasses of large antelopes, cattle and horses; it is not to be believed, however, as sometimes has been asserted, that a lion is able to "fling a bullock over its shoulder" and run away with it. Such a feat is limited to goats and small animals, if, indeed, it ever occurs. The lioness hunts by herself, especially when her kittens are young, at which time the father of the family is wandering alone, or with other males, and would be resisted if he attempted to join his spouse. The young remain with the mother until they are full-grown. The lion alone among cats is regularly polygamous, each male having three or four lionesses whose allegiance he gains by prowess in battle over rivals, and keeps by killing or driving off all newcomers. The result of these constant encounters in the arena of the desert is not only a scarcity of males but the continuous selection of the best to become progenitors of the race. One peculiarity of the lion developed by this incessant warfare among the males is the development of the defiant and terrifying voice which elevates the growl, and enlarges the scream, of other cats, into a tremendous roar—a volume of noise beyond that made by any other animal. The statement that the lion roars at stated periods appears to be almost wholly without foundation; in summer alone, and especially before storms, the lion roars before dawn. In rage the lion beats his sides with his tail, agitates his mane and facial muscles, protrudes the tongue and claws, utters the peculiar sharp, frequent growl, and altogether presents a very terrific appearance, all

LION—LIPPE

of which, primarily, has reference to the savage rivalry of males above described.

The natural disposition of all animals to get their food as easily as possible, has led lions everywhere to prey upon domestic cattle which, in a region where they are numerous, suffer nightly despoliation. Lions that have discovered this comparatively easy method of supplying their wants, soon learn that mankind is equally, or even more, readily obtainable, and become "man-eaters." Beasts so sophisticated must be put out of the way; and barbarians organize great bands of men who learn the lair of the animal, surround it and effect the animal's death by any rude means possible. Some savage hunters boldly and skilfully overcome the lion almost in single combat, with rude weapons; and white hunters face him with no greater fear than attaches to encounters with many other large animals; yet the might of the beast makes him an exceedingly formidable foe. The incessant persecution to which the lion is subjected whenever a region begins to become civilized, has exterminated it over a large part of the former domain of the species. When men began to hunt in Europe in the Stone Age, they found there lions, whose remains, entombed in the floors of caves, are called those of "cave lions" (*F. spelæus*), but which present no important differences from the modern species. Within the time of written history lions dwelt in the mountains of southwestern Europe, and many of those seen in Rome in the time of the earlier Cæsars were obtained from the Danube Valley and Asia Minor. The supply was soon exhausted, however, and the later demand was met by importations from the Caucasus and southward, but mainly from northern Africa. In the arenas of ancient Rome, large numbers of lions were frequently exhibited. Sulla, the dictator, once exhibited 100 of these animals, and Pompey presented 600 in the circus; Hadrian caused 100 to be destroyed at one exhibition, and others of the emperors and consuls were equally prodigal. In order to provide these great quantities laws were promulgated protecting the beasts in the Carthaginian provinces, to the great detriment of agriculture there, and risk of the peasantry; and breeding establishments were created to produce enough lions to meet the imperial demand. The taming and training of lions have continued ever since, and to-day this great shaggy cat is the most impressive, if not the most intelligent, of the troupe which the menagerie showman gathers about him. For a long period almost all the lions exhibited in zoological gardens and shows have been those born in captivity, where the species breeds freely.

At the present day, few lions exist north of the Soudan and Abyssinia; and they have become extinct or scarce in the civilized regions of South Africa. They no longer exist in Asia Minor, but are numerous in the extensive marshes along the lower Euphrates and Tigris, and thence occur at intervals to the valleys of the Indus, where a few still remain in the wilder deserts of Cutch and Gujarat. Formerly they were known over all northern and western India.

Books of special value relating to lions and lion hunting are Flower and Lydekker's "Mammals, Living and Extinct"; Blanford's "Zoologies" (of India, Persia and Abyssinia); Ander-

son's "The Lion and the Elephant"; Porter's "Wild Beasts"; and the hunting narratives of Gordon Cumming, Gerard, Harris, Holub, Baker and Selous.

Lion, lē-ōn, or Lyons, Gulf of, a large bay of the Mediterranean on the south of France, extending from the Spanish frontier eastward to the Hyères Islands.

Lipa, lē-pā, Philippines, a pueblo of the province of Batangas, Luzon, situated southwest of Lake Taal, 18 miles north of Batangas city. It is the junction of three important highways, all of which are old military roads, in excellent condition and always passable for heavy wagons. The town is therefore the seat of an important trade; sugar, corn and tobacco are produced, and there are drug stores and fine markets. It is one of the largest towns in the province; the people are very intelligent and progressive, and have established excellent schools; at one time a weekly newspaper was published. Pop. 14,000; municipality, 40,700.

Lipari, lē-pā-rē, or Æolian Islands, a group of volcanic islands in the Mediterranean, about 24 miles from the north coast of Sicily, situated between lat. $38^{\circ} 20'$ and $38^{\circ} 55'$ N.; lon. $14^{\circ} 15'$ and $15^{\circ} 15'$ E.; and comprised in the department of Messina. Pop. about 22,000. These islands called by the ancients Æolie, Vulcania, and Insulae Liparæorum, were supposed to be the residence of Æolus and Vulcan. Lipari, the largest, is populous and well cultivated, producing great quantities of corn and fruit, especially figs, grapes, and raisins; it likewise produces alum, sulphur, nitre, and cinnabar. It is about 15 miles in circumference; the air is healthful, the inhabitants industrious, and the males good sailors. On the eastern coast is situated a town of the same name, containing a castle built by Charles V., a cathedral, a college, several convents, and a hospital. A considerable trade is carried on in the principal produce of the island. The other islands are Stromboli, Panaria, Vulcano, Salini, Alicudi, and Felicudi, with two or three smaller ones. Volcanic eruptions ceased in the 6th century; but Lipari is composed of pumice-stone, lava, volcanic glass, and black sand; and the warm baths and heated vapors of the stoves (excavations which emit hot sulphurous exhalations) prove the activity of the subterranean fires.

Li"rogrammatic Compositions, are those in which certain letters are purposely omitted. Lope de Vega wrote a novel without an *l* or an *a*. Kotzebue wrote one without *r*.

Lipoma. See TUMORS.

Lip'ard, George, American novelist: b. Yellow Springs, Pa., 10 April 1822; d. Philadelphia 9 Feb. 1854. His most noted work was "The Quaker City" (1845), modeled on Sue's "Mysteries of Paris," and implying that Philadelphia was a modern Sodom, though he disclaimed the inference when threatened with legal consequences. Other works by him were "Mysteries and Miseries of Philadelphia"; "The Empire City: New York—Its Upper Ten and Lower Million"; "Paul Ardenheim," a Rosicrucian romance; "Legends of Mexico"; "Legends of the Revolution" (1847); "Washington and his Generals."

Lippe, lē-pē, or Lippe-Detmold, Germany, a principality, bounded north, west, and

LIPPI—LIPPMANN

south by Rhenish Prussia, and east by Hanover, Schaumburg-Lippe, and Hesse-Nassau; area, 438 square miles. It lies on the Teutoburger Wald, and is covered almost throughout by mountains and well-wooded hills, drained by the Werra, Bega, Exter, Ems, and by the Lippe. The climate is mild, but humid. Some parts of the surface are waste, or fit only for pasture, on which considerable numbers of cattle are reared; but others are fertile, producing corn, rape, hemp, and flax. The principal metal is iron, and there are quarries of limestone and gypsum, and valuable saline springs. Weaving is the chief industry, though there are also glass-works, several paper and numerous saw mills. The principal exports are wood, thread, linen, and wool. For administrative purposes it is divided into twelve bailiwicks, of which Detmold is the capital. The other chief towns are Lemgo and Horn. Since 1836 the government has been constitutional; it is a member of the German empire, and sends one member to the Bundesrath, and one to the Reichstag. Pop. chiefly Protestants (1900), 139,238.

Lippi, Fra Filippo del Carmine, frà fē-lép'pō dél kär-mē'nā lēp'pē, Italian painter: b. Florence 1406; d. Spoleto 9 Oct. 1460. In his 15th year he entered the Carmelite monastery at Florence and early formed his style on the example of Masaccio, but was later influenced by Masolino, and Angelico of Fiesole (Fra Giovanni). In 1432 he left his convent, but without release from his vows. His relations with Lucrezia Buti, whether a nun or not, are largely unverified romances of Vasari, and modern biographers are not inclined to believe them. In his best work he united with the spiritual feeling of Fra Angelico of Fiesole, the strong historic imagination, energetic modeling, and unconventional loveliness of form and face, characteristic of Masaccio. His greatest masterpiece is in the parish church of Prato, and consists of a series of frescoes illustrating the life of St. Stephen, John the Baptist, etc. Many of his altar-pieces are now in the Florentine Academy. His last frescoes in the Cathedral at Spoleto were executed with the collaboration of Fra Diamante. Examples of this painter are also to be found in the galleries of Berlin, Munich, and Rome.

Lippi, Filippino, fē-lē-pē'nō, son of the preceding by Lucrezia Buti, Italian painter: b. Prato 1457 or 1458; d. Florence 18 April 1504. He was a pupil of Fra Diamante, but seems to have closely followed the artistic example of his father and Sandro Botticelli. Among his wall paintings, which show a wonderful advance beyond his predecessors, are those in the chapel of the Brancacci family at Florence, in which is portrayed the history of SS. Peter and Paul, and the decoration of the walls of the Church of Santa Maria Sopra Minerva, at Rome (1489) illustrating the life of Saint Thomas Aquinas. His masterpiece, however, is to be found at Florence in the Strozzi chapel of Santa Maria Novella, where his frescoes portray the legendary life of the Apostles Philip and John (1502). Some of his smaller canvases are in the galleries of Florence, Bologna, Berlin and Copenhagen.

Lippi, Lorenzo, lō-rēnd'zō, Italian poet and painter: b. Florence 1616; d. there 1664. He published a comic epic poem in 12 cantos,

'Il Malmantile vacquisdato' under the anagrammatic pseudonym, "Perloni Zipoli" (1676). The poem abounds in rare humor and is written in light, swift verse. The language, however, abounds in Florentine provincialities, and is unintelligible without such a commentary as is furnished to the edition of 1688 by P. Munucci. As a painter he was an imitator of Santi di Tito's manner. There is a 'Crucifixion' of his in the Uffizi gallery at Florence; and 'The Triumph of David'; and 'Christ and the Woman of Samaria' are in the Imperial gallery at Vienna.

Lippincott, lip'in-kōt, Joshua Ballinger, American publisher: b. Juliustown, N. J., 1816; d. Philadelphia 5 Jan. 1886. He was a bookseller in Philadelphia 1831-6 and in the last named year founded the house of J. B. Lippincott & Co., which by 1850 was at the head of the book trade in Philadelphia. After his death, in 1886, the firm was converted into the J. B. Lippincott Company. 'Lippincott's Magazine' was established in 1868.

Lippincott, Sara Jane Clarke, "GRACE GREENWOOD," American writer: b. Pompey, N. Y., 23 Sept. 1823; d. New Rochelle, N. Y., 20 April 1904. She was married in 1853 to L. K. Lippincott of Philadelphia. She first became known as writer for young people over the signature "Grace Greenwood." She edited for many years 'The Little Pilgrim,' a paper for juvenile readers, lectured on anti-slavery and other reform movements, and corresponded for various New York journals. She published 'Greenwood Leaves' (1850); 'Poems' (1851); 'Merrie England' (1855); 'Records of Five Years' (1868); and 'New Life in New Lands' (1873); 'Victoria, Queen of England'; 'Recollections of My Childhood'; etc.

Lippincott, William Henry, American artist: b. Philadelphia, Pa., 6 Dec. 1849. He began his art studies in the Pennsylvania Academy of Fine Arts, and his first professional appearance was as a book illustrator and later as a scene painter. In 1874 he became the pupil of Bonnat and for the eight years he remained at Paris exhibited annually in the Salon. The wide range of the work which he has done since he took up his residence in New York includes portrait, genre, landscape and scene painting, and he appears regularly as an exhibitor in the annual American art exhibitions. His most important pictures include 'The Duck's Breakfast'; 'Un Jour de Congé'; 'Pink of Old Fashion'; 'Helena'; 'Infantry in Arms'; 'Love's Ambush'; and 'Pleasant Reflections.'

Lip'pitt, Charles Warren, American manufacturer and politician: b. Providence, R. I., 8 Oct. 1846. He was graduated from Brown University in 1865 and in 1869 entered his father's woollen establishment. He has held various local posts of honor, such as president of the Providence Board of Trade, 1881-2, and has been president since 1896 of the Rhode Island National Bank. He was governor of Rhode Island, 1895-7.

Lippmann, lip'man, Julie Mathilde, American author and critic: b. Brooklyn 27 June 1864. She received an academic education and began writing at an early age. She has contributed to the leading American magazines; and has written verse and juvenile stories. Her publications include 'Through Slumbertown,

LIPTON—LIQUOR TRAFFIC

and Wakefield' (1891); 'Jock o'Dreams' (1891); 'Miss Wildfire' (1897); 'Dorothy Day' (1898); 'Sweet Ps' (1902); 'Dearie, Dot, and the Dog' (1903); 'Del's Debt' (1903); also the plays 'A Fool and his Money' (1897); 'Cousin Faithful' (1897); and 'The Facts in the Case' (1897).

Lip'ton, Sir Thomas Johnstone, Irish merchant and yachtsman: b. Glasgow, Scotland, 1850. He came to America as a steerage passenger in 1865, for two years worked in the South Carolina rice fields, later in various northern towns, opened a provision shop in Glasgow, attained great business success and finally organized the "Lipton, Limited," the largest commercial establishment in the United Kingdom, where it controls 420 shops. This business is capitalized at \$200,000,000, with tea, coffee, and cocoa estates in India and Ceylon, fruit-orchards in Kent and elsewhere, and a packing-house and refrigerator-car line in Chicago. Lipton has given largely for charitable purposes, including \$125,000 in Diamond Jubilee year (1897) for a dinner fund for the poor, and \$500,000 toward the Alexandra trust for supplying working-people with cheap dinners. He is best known, however, for his efforts as a representative of the Royal Ulster Yacht Club to obtain the America's Cup in the international yacht-races of 1899, 1901, and 1903. His three British-built yachts were in each contest defeated in three straight races, by the Columbia in 1899 and 1901, and by the Reliance in 1903. He was knighted in 1893, and made a baronet in 1902.

Liquefaction of Gases. See **GASES, LIQUEFIED, USE OF.**

Liqueur, li-kér' (the French name), a palatable spirituous drink composed of water, alcohol, sugar, and some aromatic infusion extracted from fruits, seeds, etc. The great differences in the qualities of the different liqueurs are owing principally to a variation in the proportions of the sugar and alcohol. The French distinguish three qualities: the first are the *ratafias* or simple liqueurs, in which the sugar, the alcohol, and the aromatic substance are in small quantities: such are the anise-water *noyau*, the apricot, cherry, etc., ratafias. The second are the oils, or the fine liqueurs, with more saccharine and spirituous matter, as the *anisette*, *curacao*, etc. The third are the creams or superfine liqueurs, such as *rosoglio*, *maraschino*, Danzig water, etc. The same aromatic infusion may therefore give its name to liqueurs of different qualities, in which the materials are the same but the proportions different.

Liquid Air. See **AIR; GASES, LIQUEFIED, USE OF; TRIPLER, C. E.**

Liquidambar, lik'wid-äm"bar, Sweet, Red, or Star-leaved Gum, a tree (*Liquidambar styraciflua*), also called bilsted and alligator-tree, of the witch hazel family widely diffused through North America, from lat. 43° to Florida, and along the shores of the Gulf into the provinces of Mexico. The leaves are five-lobed, and the lobes are pointed, and serrated on the margin, giving them a very distinct and elegant form, and in autumn they turn rich purplish red. The flowers are inconspicuous. The fruit consists of a hanging ball of woody pointed pods which open and release the seeds,—a most singular and characteristic fruit, suggesting the globular spiked head of the mediæval war-club called

"morning star." The usual diameter of the trunk is from 1 to 3 feet. The wood is compact, capable of receiving a fine polish, and has been used for articles of furniture. The bark has a habit of forming wing-like projections on the twigs, unlike any other American tree, on being wounded yields a small quantity of a fragrant resin (storax or styrax), which contains benzoic acid. Most of the liquid storax used in pharmacy, however, is obtained from Trieste, and is collected from *L. orientale*, the "lord-wood" of the Cypriots, which grows throughout the Levant.

Liquids, Compressibility of. It was long supposed that liquids were perfectly incompressible. In the Florentine experiment a hollow globe of gold or lead was filled with water and the hole soldered. When the globe was crushed, so that its volume was diminished, some water forced its way through the metal and appeared like dew on the outside, and it was hence concluded that water was not susceptible of compression. Oersted, however, disproved these conclusions. His piezometer, which was a bulb at the end of a graduated capillary tube, was nearly filled with water, a small thread of mercury being at the end of the column of water in the tube. The relative volumes of the bulb and tube were known. The piezometer, along with a small air manometer, was surrounded with water inside a strong glass vessel. The water filled the vessel, and might be subjected to great pressure by means of a screw. When the screw was turned, the position of the mercury thread showed the water in the piezometer to be compressed; and comparison with the manometer enabled the compressibility to be found. Oersted's method is not exact enough. The following results are those of Grassi, who employed Ragnault's improvement on Oersted's method. The pressure of one atmosphere caused

Mercury at 0° C.	to shrink 3 millionths of its volume.
Water at 0° C.	50 "
Water at 41.6° C.	44 "
Ether at 0° C.	111 "

Liquor Laws and License. See **INTERNAL REVENUE; LOCAL OPTION.**

Liquor Traffic. The use of alcoholic beverages in the United States has increased 100 per cent since 1880. In 1902, the consumption of liquor amounted to 19.48 gallons per capita. The use of the milder stimulants has not grown so fast, that of coffee rising from 8.78 pounds per capita to 13.37 pounds, a little over 52 per cent, while tea dropped from 1.39 pounds to 0.94 pound, a decrease of nearly 48 per cent. The supplanting of the milder for the stronger stimulants does not indicate greater national regard for better social and higher physical conditions.

The total bill of the American people for stimulants in 1902 was \$1,396,008,276; the average yearly expenditure for the previous five years, \$1,239,108,955. The record for 1902 represents a per capita expenditure for stimulants of \$17.33 for the 79,003,000 inhabitants of the United States, or 4.7 cents per day. The users of alcoholic stimulants are estimated to form one fourth the total population, on which basis the per capita cost of alcoholic beverages is \$69.32, or 19 cents per day.

Bringing together into one group the cost at retail of all beverages, we find that the United States consumed in 1902 alcoholic and non-

LIQUORICE — LISBON

alcoholic stimulants to the value of \$1,369,098, 276, as follows:

Alcoholic drinks	\$1,172,565,235
Non-alcoholic stimulants —	
Coffee	\$149,891,030
Tea	39,642,011
Cocoa	7,000,000
	196,533,041
Total, 1902	\$1,369,098,276
Total, 1901	1,273,212,386
Total, 1900	1,228,674,925
Total, 1899	1,146,897,822
Total, 1898	1,177,061,366

The quantities of the four leading beverages consumed for the year ending 30 June 1902, were as follows:

	Gallons
Coffee	1,498,910,304
Beer	1,381,875,437
Tea	396,420,115
Spirits and wines	157,206,554

The latest report of the United States Bureau of Statistics shows the per capita consumption of liquors in this country:

	Spirits Gallons	Wine Gallons	Beer Gallons	Total Gallons
1892	1.51	.44	15.17	17.12
1893	1.52	.48	16.20	18.20
1894	1.34	.31	15.32	16.97
1895	1.13	.28	15.13	16.54
1896	1.01	.26	15.38	16.66
1897	1.02	.53	14.94	16.50
1898	1.12	.28	15.96	17.36
1899	1.17	.35	15.28	16.80
1900	1.27	.40	16.01	17.68
1901	1.33	.37	16.20	17.90
1902	1.36	.63	17.49	19.48

Coffee continues to hold first place in the affections of the American people. Its low cost stimulates demand and makes it a formidable competitor of alcoholic liquors and malt beverages. The use of beer, wine and spirits shows considerable gain over 1901 — a notable fact in view of the great prosperity of the United States. See BEER; COFFEE; TEA; WHISKEY; WINE; ETC.

Liquorice. See LICORICE.

Liquors, a term applied to alcoholic or spirituous fluids whether distilled or fermented. Alcoholic liquors are usually divided into three groups, viz., the fermented, the malt liquors, and the distilled liquors. The first of these include those wines and liquors which are made from the juice of fruits and in which the natural sugar is converted into alcohol by exposure to the open air. The second class includes such as ales, porter and beer in which the starchy ingredients are by certain processes changed into sugar before fermentation can take place. The third division includes brandies, whiskies and gin, and whether these be derived from fruits or grain the distillation process is carried on further by condensation and vaporization.

Wine Manufacture.— Wine needing no machinery for its manufacture is the oldest of beverages. It was early made by the Greeks and Romans who exercised the greatest care in its preparation, often flavoring it with spices and herbs. The early settlers of this country naturally set about its manufacture almost simultaneously with their landing, but it was not until about 1880 that the wine industry received any impetus, and since that time it has rapidly

increased. The California wine industry which is little more than fifty years old gives employment to 60,000 persons and represents a combined capital of \$72,000,000. The largest vineyard in California and also the largest in the world was owned by the late Senator Leland, founder of the Leland Stanford Junior University. It comprised nearly 5,000 acres.

Manufacture of Malt Liquors.— The consumption and manufacture of malt liquors in America increased very slowly principally on account of the introduction of tea and the household manufacture of ciders and fruit brandies. The manufacture of beer in the United States began about 1840, and the number of breweries for making of malt liquors has increased from 431 in 1850, to about 1600 in 1903. The development of this branch is due chiefly to the energy of the Germans. The chief cities for its manufacture are Milwaukee, St. Louis, Cincinnati, Rochester, Pittsburgh and Kansas City.

Manufacture of Distilled Liquors.— The steady growth of this industry is not so marked as that of wine and malt liquor manufacture.

The distilleries are scattered about 28 different States, among which Illinois produces the largest amount, with Kentucky, Indiana, Ohio, Pennsylvania and Maryland following in order named. For statistical information see U. S. government reports 1903.

Lira, lē'rā, an Italian silver coin valued at about 18 cents in American money. It is the basis of the Italian monetary system; the gold coins are pieces of 100, 50, 20, 10, and 5 lire; the silver coins, of 5 and 2 lire, besides 1 lira and a half lira (50 centesimi); also lower coins in nickel and bronze.

Lir'ioden'dron. See TULIP TREE.

Lisaine, lē-zān, Battle of, an engagement of the Franco-German war, 15-17 Jan. 1871, on the banks of the Lisaine River near Belfort (q.v.). See BOURBAKI CHARLES DENIS SAUTER.

Lisbon, liz'bōn, Ohio, village, county-seat of Columbiana County; on the Beaver River, and on the Erie Railroad; about 130 miles northeast of Columbus. It is situated in an agricultural region with extensive coal-fields in the vicinity. Sheep and cattle raising, the cultivation of grain and vegetables, and mining are the prominent occupations in this section. Lisbon is the trade centre for a large portion of the county. The village owns and operates the waterworks. The public library has about 4,000 volumes. Pop. (1890) 2,278; (1900) 3,330.

Lisbon, Portugal, the capital and principal seaport on the right bank of the Tagus, about 9 miles above its mouth. It is built on a succession of hills, rising from the quays in the form of an amphitheatre. The streets of the older parts, more especially in the east, are steep, narrow, crooked, badly paved, and dirty; the houses, with a few exceptions are old-fashioned and mean. The modern portion, however, which lies on even ground, in the valley between the Monte do Castello on the east, and the hills of San Francisco and Do Carmo on the west, consists of several parallel streets crossed by others at right angles, and is regular, well built, clean, traversed by street railways, electrically lighted, and provided with a telephone service. Of these the D'Ouro (Gold), Do Prato (Silver), D'Augusta, Do Chiado (Cloth) streets extend about one half mile, north to south, hav-

LISBURN — LISZT

ing at their southern extremity the Praça do Comercio, a large and handsome square, surrounded on three sides by the naval arsenal, the exchange, custom-house, and other public buildings, and having the Tagus on the south. At the northern extremity of these streets are the Praça da Figueira, a picturesque square, used as a public market, and a handsome square called the Rocio or Praça de Dom Pedro IV., with a fine bronze statue of Dom Pedro IV., surmounting a tall marble column. To the northwest extends, for nearly a mile, a broad avenue, the Avenida da Liberdade, lined with handsome houses, and planted with shrubs, etc. Besides this the finest open spaces are the Estrella Gardens, the Botanic Garden, the Praça do Príncipe Real and that of Pedro de Alcantara. The western quarter called Buenos Ayres, is airy and pleasant, and here foreigners chiefly reside. The town of Belém, on the west, beyond the river Alcantara, forms a sort of suburb to Lisbon. It has a well-known tower, forming one of the defenses of the harbor. The principal residence of royalty is the Ajuda Palace, built of white marble on the summit of a hill. The castle of St. George is remarkable for the beauty of its situation. Other noteworthy buildings are the cathedral, once a Moorish mosque, on the slope of the Castle Hill, on the east; the church do Coração de Jesus, surmounted by a splendid dome; the church of the Martyrs, erected on the spot where Alfonso I. mounted the walls of the city and rescued it from the Moors; the handsome church of Santa Engracia; the church and monastery of Belém; and the church of San Roque. The numerous convents which crown the hills, and appear like palaces and fortresses, are for the most part massive and imposing structures. But unquestionably the most remarkable specimen of architecture is the aqueduct which conveys water to the city from springs rising near the village of Bellas, about 6 miles distant. It is partly conducted underground, but on approaching Lisbon it crosses the deep valley of Alcantara, which is spanned for nearly 2,500 feet by a bridge of thirty arches, the loftiest of which is 240 feet high and 110 feet wide. An additional supply is brought in by another series of works from a distance of 18 miles. The scientific and literary institutions comprise the Royal Academy of Sciences, founded in the latter part of the 18th century; the well equipped Polytechnic School, with a museum, botanic garden, and observatory; an academy of medicine and surgery; institute of agriculture and veterinary medicine; Royal Marine Academy; Royal Military College, School of Music, National Library, containing about 300,000 volumes, and that of the Academy of Sciences, numbering about 80,000 volumes; the Royal Schools of Vicente de Fora; Royal School of Drawing and Architecture. The harbor, or rather the roadstead, is one of the finest in the world; and the quays, which extend between two and three miles along the bank of the river, are elegant and commodious. The exports consist chiefly of wine, oil, fruit, cork, fish, onions and other vegetables, and salt; and the principal imports are grain, silk, linen, cotton, and woolen cloths, iron, steel, hardware, dried fish, petroleum, colonial produce and coals. An aggregate of about 6,000 vessels of over 7,000,000 tons enter and clear the port annually. The manufactures include various textile goods, tobacco, paper,

chemicals, and soap; there are also sugar-refineries, iron-foundries, and potteries.

Lisbon was anciently called Olisipo. Felicitas Julia was its name under the Romans. It was captured by the Moors in 716, and remained in their possession till 1147. In 1755 it was visited by the historic and terrible earthquake, which threw down a considerable portion of the city, and destroyed above 30,000 of its inhabitants. It was taken by the French in 1807, but resisted an attack by Masséna in 1809. Pop. (1900) 357,000.

Lisburn, lis'bērn, Ireland, a market-town in the counties of Antrim and Down, 8 miles southwest of Belfast, on the river Lagan. It is in general well built, and has a clean and thriving appearance with a market-house and court-house; the episcopal cathedral church of the united dioceses of Down, Connor, and Dromore, containing a monument to Jeremy Taylor, who died here in 1667; a Roman Catholic church and other places of worship; county infirmary; new people's park, etc. Flax spinning and weaving, and the manufacture of thread, muslin and damask, employ the greater number of inhabitants. Pop. (1901) 11,459.

Lissajous's (lē-sā-zhoōz') Figures. A ray of light is reflected from the limb of an upright tuning-fork to the limb of a horizontal tuning-fork, and thence to a screen, a point of which it illuminates. When the tuning-forks vibrate, if they are perfectly in unison the spot on the screen describes a straight line, or a circle, or an ellipse, but if not, various complex curves are described. See Acoustics; VIBRATION.

Lis'ter, Joseph, English surgeon: b. Upton, Essex, 5 April 1827. He was graduated M. B. of London University in 1852, becoming in the same year a fellow of the Royal College of Surgeons. For a few years he lectured on surgery in Edinburgh, and from 1860 to 1869 was professor of surgery in Glasgow University. He was professor of clinical surgery in the University of Edinburgh, 1869-77, and filled the corresponding chair in King's College, London, 1877-92. His name is especially connected with the successful application of the antiseptic treatment in surgery, which inaugurated a new era in this branch of medical science. He received the prize of the Academy of Paris, and the medal of the Royal Society in 1880. In 1883 he was made a baronet, and in 1897 was raised to the peerage. He has published papers on surgical pathology, etc.

Liszt, Franz, frānts list, French pianist and composer: b. Raiding, near Odenburg, Hungary, 22 Oct. 1811; d. Bayreuth 31 July 1886. He was scarcely nine years of age when he made his first appearance as a pianist and improvisator in Odenburg and Presburg with such success, that several noblemen undertook the expenses of his training at Vienna under Czerny the pianist, and Salieri the composer. In 1823 he made a great sensation as executant and improvisator on the piano in Vienna, Munich, Paris and other cities. His father thereupon traveled with him through France, Switzerland and England for further study of his art. While yet a boy he composed the operetta 'Don Sancho' (1824) and the following year launched out into grand opera at Paris. His hearing of Paganini in 1831 affected him greatly and had a most stimulating influence on his

LIT DE JUSTICE—LITANY

cultivation of virtuosity. At this time he experienced the conflict, between his religious pre-dilections and his father's wishes for his musical success, which resulted in his yielding to the latter's advice and adopting the profession of music instead of studying for the ministry. In 1835 he had completed his studies as composer for the piano, and in company with the Countess d'Agoult, who afterward became the mother of his children, he began his travels, during which he gave a series of concerts in Switzerland, Italy, and Hungary, winding up with some remarkable performances in Vienna. From 1839 to 1847 he made a triumphal progress through the whole of Europe. His success was due less to the astounding power of execution with which he rendered the masterpieces of every age, than to the sublimity, the noble feeling, the depth of expression with which he rendered every number of his programme. Honors now were showered upon him; he was made Kapellmeister to the Grand Elector of Weimar; Frederick William IV. knighted him, and he was decorated by every court in Europe. From this time (1848) to 1861 he worked at Weimar as the teacher and "inspirer" of a large circle of young musicians. He then settled in Rome. In 1870 he was made president of the Royal Musical Academy at Budapest and henceforth lived in turn there, at Rome and at Weimar. The villa in the last city which he occupied now contains the Liszt museum.

In the career of Liszt as a composer there are three distinct periods. The compositions of his first period consist partly of "Transcriptions" for the pianoforte (a department in piano music inaugurated by him); partly of piano pieces, songs and choruses for male voices. In the second period, during his residence at Weimar, he applied himself to purely instrumental music, in accordance with the principles which he had learned of Berlioz. He sought on the piano to express by a symphony familiar poetic objects and by means of this to adumbrate ideas of a lyric or dramatic order. To this class of compositions belong his twelve "Symphonic Poems," namely, (1) "Ce qu'on entend sur la Montagne" known also as "The Mountain Symphony"; (2) Tasso's "Lamento e Trionfo"; (3) Preludes, after Lamartine's "Notre Vie est-elle autre Chose qu'une Serie de Preludes"; (4) "Orpheus"; (5) "Prometheus"; etc. Later in this period appeared "Missa Solemnis" and "The Hungarian Coronation Mass." In his third period, from his residence in Rome to his death, he is chiefly remarkable as a composer of sacred music. He produced the oratorios "Christus"; and "The Legend of Saint Elizabeth"; a "Requiem," for male voices and the organ; besides "Cantatas," "Psalms," "Paternosters," and short pieces for the church choir. In all these works he followed the method inaugurated by Berlioz and Wagner, and his works indicate the high water mark of the North German school. What perhaps won him most renown were his "Symphonic Poems" and his sacred compositions, in which latter he strove to blend the liturgical and dramatic elements of music. He was also a musical critic of considerable power. Among his published works may be enumerated: "Frederic Chopin" (1852); "Lohengrin et Tannhäuser de R. Wagner" (1851); and "Les Bohémiens et leur musique en Hongrie" (1859). Consult: Ramann, "Franz Liszt als Künstler und

Mensch" (1893); Voegel, "Franz Liszt" (1888); Von Lenz, "Great Piano Virtuosos" (1899); and Fay, "Music Study in Germany" (1880).

Lit de Justice, lē dé zhüs-tēs, formerly a solemn proceeding in France, in which the king, with the princes of the blood royal, the peers, and the officers of the crown, state, and court, proceeded to the parliament, and there, sitting upon the throne or lit, caused those commands and orders which the parliament did not approve to be registered in his presence. The parliament had the right of remonstrating in behalf of the nation against the royal commands and edicts. Louis XV. held such a lit de justice in 1763, in order to introduce certain imposts, but on account of the firm resistance of the parliaments he was finally obliged to yield. The last lits de justice were held by Louis XVI. in 1787 and 1788.

Litany (from the Greek *litaneia*, supplication, prayer), a form of prayer or song, first especially used on occasions of public calamity, and introduced according to Zonaras and Nicephorus, by Proclus, about the year 446, at Constantinople, in the reign of Theodosius; according to Paulus Diaconus, under Justinian, at Antioch, in consequence of the following circumstance: An earthquake, says the legend, having driven the people into the fields, a boy was suddenly taken up into the air in their presence, but was again let down unhurt, on the people crying out "Kyrie eleison!" (O Lord, have mercy). The boy related he had heard the song of the angels, "Holy God! Holy and Mighty, Holy and Immortal! have mercy upon us!" and this gave rise to the Litany. This kind of common prayer was perhaps not unusual among the Jews, and Psalm cxxxvi. seems to have been adapted to this purpose.

The litanies in general use in the Roman Catholic Church are the "Litany of the Most Holy Name of Jesus," the "Litany of the Saints" and the "Litany of Loreto." The "Litany of the Most Holy Name of Jesus" is composed of a series of addresses to Jesus Christ, using the different names by which He is called. Like all the litanies it begins with "Kyrie eleison" (Lord have mercy) and ends with an entreaty to the "Lamb of God who taketh away the sins of the world." This litany is said aloud in the churches by the members of the "Holy Name Societies" on general communion days. The "Litany of the Saints" is composed of supplications to God for favors and to return thanks, and a number of petitions to saints asking their intercession. This litany is a part of the special church service for Saint Mark's day, the rogation days, the rubrics for the consecration of churches and cemeteries, for ordinations and for other church services. The "Litany of Loreto" receives its name from being sung on Saturdays and feasts of the Virgin Mary, in the Santa Casa of Loreto. It consists of a number of petitions to the Virgin Mary using her different titles as found in the Scriptures and in sacred writings, and asking her intercession.

Litanies are found in the old hymn-books of the Lutherans, but are no longer used by Protestant Germans. In the Anglican prayer-book the litany is retained, and though it adheres in many respects to the ancient forms, it differs from that of the Roman Catholic Church, and contains no

LITCHFIELD — LITERARY LABOR-SAVERS

invocation of the Virgin or the saints. Since 1661 it is no longer a distinct service, but, when used, forms part of the morning prayer, after the third collect for Grace.

Litchfield, lich'fēld, Grace Denio, American novelist: b. New York 19 Nov. 1849. She has lived in Europe for a number of years, but since 1888 has resided in Washington, D. C. Her works are: 'Only an Incident' (1883); 'The Knight of the Black Forest' (1885); 'Criss Cross' (1885); 'A Hard-Won Victory' (1888); 'Little Venice' (1890); 'Little He and She' (1893); 'Mimosa Leaves' (1895); 'In the Crucible' (1897); 'The Moving Finger Writes' (1903).

Litchfield, Conn., borough, one of the county-seats of Litchfield County; near Bantam Lake, and on the Shepaug, Litchfield & Northern railroad; about 15 miles northwest of Waterbury and 28 miles west of Hartford. The first settlement was made in 1719, and the place was called Bantam, but after a few years the name was changed to Litchfield. During the Revolutionary War the place was used for storage of supplies. The women of Litchfield melted and made into bullets the statue of George III. which the people of New York city had torn down from Bowling Green on 9 July. Sarah Pierce opened here, in 1792, a school for the higher education of women. Judge Topping Reeve, in 1784, opened here the first law school in the United States. It was patronized by many young men who afterward became prominent in the affairs of the nation. It was the birthplace of Ethan Allen and of Henry Ward Beecher and Harriet Beecher Stowe. Lyman Beecher was a pastor here for 16 years beginning with 1810. Litchfield is situated in a region where grazing and dairying are the prominent industries, but valuable deposits of nickel ore are found in the vicinity. The beautiful scenery, beautiful and mild climate, make it a favorite pleasure resort. The chief industrial establishments are nickel-smelting works and creameries. Bantam Lake, nearby, is the largest in the State. Pop. (1900) 1,120.

Litchfield, Ill., city, in Montgomery County; on the Illinois Central, the Cleveland, C. & St. L., the Wabash, the Chicago, P. & St. L., the Chicago & A., and the Jacksonville & St. L.; about 50 miles northeast of Saint Louis, Mo., and 45 miles south of Springfield. It is in a good farming section, with oil, coal, and natural gas in the vicinity. The chief industries are mining and manufacturing. The principal manufactures are railroad cars, foundry products, glass, briquet ornaments, mine engines, brick, tile, flour, and lumber. The trade is in the manufactures, coal, oil, and some farm products. It has good schools, a public library, and several prominent buildings. The government is vested in a mayor whose term of office is two years, and in a council, with administrative officials appointed by the mayor and approved by the council. Pop. (1900) 5,918.

Litchfield, Minn., village, county-seat of Meeker County; on the Great Northern railroad; about 63 miles west of Saint Paul. It is situated in an agricultural and stock-raising region. Its chief industries are connected with farm products and the shipping of live stock. It has machine-shops, flour and lumber-mills,

wagon and carriage factory, a foundry and brick yards. Pop. (1900) 2,280.

Litchi, lich'i, or Lee-Chee, a tree (*Nephelium litchi*) of the horse-chestnut family, native to southern China. It is of moderate size, with brown bark, large leaves, and fruit produced in bunches, which are pendant from the extremities of the twigs. Each berry, known in trade simply as "litchi," is 1 to 2 inches in diameter, with a tough, thin, leathery coat, and a colorless half-transparent pulp, in the centre of which is a single brown seed. The fresh fruit is pleasantly sweet and reputed to be one of the most delicious known. It is sold extensively in America and Europe in a dried state, and though the pulp is much diminished in size it retains a considerable portion of its original flavor. Attempts have been made to cultivate it in the United States with some success in southern California and at Key West, but the tree seems extremely susceptible to chilling. Other species of *Nephelium*, as the longan tree (*N. longanum*) of the East Indies, yield similar fruit, and seem better adapted to American cultivation; its nuts are smaller and less sugary than those of the litchi, but are regarded by the Chinese, by whom they are also cultivated, as having useful medicinal qualities.

Liter. See **LITRE**.

Literary History, the history of books, treating therefore the attainments and progress of the human mind in every department, and the characteristic tendencies and opinions of every age. Political and ecclesiastical histories deal chiefly with events; literary history, with thought; each merges into the other, and they are necessarily connected in any complete narrative. Bibliography, biography, and even special criticism are but the subordinate parts of literary history; its main object is to show the general progress and phases of intellectual development and of æsthetic and moral culture. The ancients left no example of this species of history. It consists in large part of generalizations from literary phenomena, of which Paterculus gives one early instance. He shows by a historical review that the great men of antiquity seem often to have come in clusters, appearing almost contemporaneously in particular places. Quintilian also introduces the principal authors of Greece and Rome together in a single chapter. But the classical and mediæval authors rendered scarcely any service to this department, except by leaving materials. The principal attempts in the 17th century were the 'Prodromus Historiæ Literariæ' of Lambecius (1659), in which the design of a universal account of literature is completed only as far as the times of Moses and Cadmus, and the 'Polyhistor Literarius' of Morhof (1688), a work of erudition and judgment, which was enlarged by Fabricius, and remained long in esteem. From the 16th century many more or less comprehensive histories of European literature have appeared, and the 19th century especially produced valuable synoptical views both of European and Oriental literature.

Literary Labor-savers, Library Utensils, and Mercantile Office-fixtures. Man goes from barbarism to civilization by learning to do things better, quicker, easier, or more cheaply. Some labor-savers combine two or

LITERARY LABOR-SAVERS

more of these improvements. America leads the world in prosperity because it led in adopting standard sizes for parts of machinery and in other labor-saving methods and devices. Obviously by as much as services of high salaried men who work at desks are more valuable than those of mechanics, by so much are literary labor-savers worth more to the world than the highly prized machines of manufacture and commerce. Yet it was not till a library supply bureau was founded in Boston in 1876 that this was practically recognized. Since then there has been marvelous development, till now a device for saving money, time or labor in office, library or study is valued as highly as one for factory, shop or farm.

This article aims to be practical, not historical, and to call attention to a few less prominent things useful to those aiming to accomplish most intellectual labor with their time and strength. Space allows only dogmatic statements when convincing reasons based on long tests and special studies could easily be given. These experiments are constantly in progress in connection with the New York State Library School, at Albany (see LIBRARY SCHOOLS), which has in its museum of labor-saving methods and appliances the entire collections and World's Fair exhibits of the American Library Association organized in 1876, the aim being to give information as to which of the countless devices and new methods are really worth adoption.

Hundreds of ingenious, practical labor-savers for technical uses will be brought to attention of those needing them by their promoters. Electric and other tabulating and computing machines illustrate immense savings made possible by such devices, which are as important to desk workers as sewing-machines to seamstresses or improved tools to mechanics. If the principle is admitted that time and labor should be saved for brain work as for hand work, it follows that the minutest saving is worth attention. Many factories make their entire profit by using an improved method or machine, or by utilizing waste in some by-product. In offices with many clerks, a method by which four motions do the thing formerly taking five, saves a considerable aggregate in salaries each year.

Writing and Printing.—Writing is easily the greatest of human inventions. All nations recognize this in their traditions by attributing to it divine origin. Some 5,000 years ago Egyptian priests evolved pictures of things into ideograms or pictures of abstract qualities and ideas, then pictures for sounds of words or syllables (where some Eastern languages still stop); and finally pictures for sounds of final elements or single letters. The surfaces on which these were written were evolved from stone, horn, clay, metal, wood, wax, bamboo, and birch-bark, skins, and papyrus, till we reached that wonderful product, paper. The first writing implement, of flint, was followed by the stylus, fine brush of hairs, split reed, quill, steel and gold dip pens, which in turn are now being superseded by fountain pens and typewriters. After inventing writing, the ancients devised abbreviation systems as labor-savers. Then came the faster forms of letters for cursive writing which we call small or lower case. Taking less space and being both written and read more quickly, they

have already largely displaced capitals, with a growing tendency to displace them still farther. The next step was a combination of greater abbreviation and greater simplifying of forms by stenography, which was revolutionized and systemized by Isaac Pitman. (See STENOGRAPHY.) The greatest invention after writing was printing, followed by telegraph, cable, and telephone, which, in universal use, suggest what the human mind has already done and possibilities of further growth.

Model Office or Study.—A southeast corner room is best; north light is most uniform; west least desirable. Health forbids carpets in public rooms. Use hardwood floors, or corticine, which is cheap, durable, easily washed, deadens noise, and is warm. Hot water is best for heat, being free from the quick changes and annoying cracking usual in steam. For ventilation, have both inlet and outlet flues, with open fire if practicable. If not, insure circulation through flues by gas jets, pipes, or motors. Desks should stand with windows at left. The popular roll-top darkens the desk top. The roll, if needed, is better over pigeonholes, which are best for space in front of the chair if one has many papers, as they allow the largest number of boxes to be reached most quickly. Pigeonholes are best where quick work is the chief end, but catch more dust than drawers and take more space than vertical files which hold on edge papers, pamphlets, and clippings, and are cleanest, cheapest, and best for most storage. Space not needed for pigeonholes in front of the desk is best used for vertical files or drawers. Telephone and desk light (with green porcelain shade to protect the eyes) should be on arms, to swing out of the way when not in use, and save desk space. Standard size pigeonholes, drawers, trays, and shelves should fill all blank wall space at left and behind, within reach from the swivel-and-spring desk chair. Some find a chair with curved spring back a help. Upholstery is heating and sometimes dangerous for constant use.

A model desk is 78 cm high, not 75 as is common. Drawers run to floor without baseboard and clear through to back and have side runs with no cross pieces. At no extra cost this gives easier action and maximum storage. All drawers are at least 9 cm deep inside to hold standard card trays. The centre opening for the feet is at least 60 cm wide with a centre drawer large enough for 50x60 cm standard large sheets often needed for charts and tables. Rows of drawers each side the chair have slides above them, as long as possible. On small desks extension leaves supported by folding brackets may be added to either end. Tops are 60 to 100 cm wide. The usual length, 150 cm [60 in.] is the largest top easily reached from the chair.

Office bells should be single stroke, not buzzers, to allow simpler codes of time-saving signals. Barometer or fountain sponge cup and mucilage stands save labor. If inkstands are used, the Perfect or some other pattern that prevents evaporation and so requires no refilling till ink is all used, is important. Self-inking rubber stamps for any words or dates often written save much time and give more distinct entries. If several are used they must be kept in racks plainly labeled or it takes as long to find the right one as to write the words. A metal

LITERARY LABOR-SAVERS

straight edge exactly P size is much quicker than shears and ruler in fitting clippings and parts of sheets for trays. Printed blanks for everything much used, with alternatives both printed so that instead of filling in words, a single stroke crosses out those not wanted, reduce labor immensely. Printing is cheap, clerical labor costly. A letter sheet with months at the head of 12 columns, ruled with 31 numbered lines, gives a square for each day in the year and is invaluable for statistics or records.

Vertical writing, disjoined, is more like print and can be written as fast as the sloping hand which is so much less legible that libraries prohibit it on catalogue cards. Blotting blurs the sharp lines of writing and takes away some color. Ink should dry naturally. Odd size envelopes are a nuisance and go less safely in mails than standard sizes, as they project and are torn or crumpled in the post-office when tied in bundles. For notes and P cards use No. 5½, for 4P sheet (15 x 25 cm) No. 6½, for letter-sheet No. 8½. Never use for manuscript a sheet wider than 20 cm. Science proves this line twice too long for easiest reading, the best width of paper being 12.5 cm.

Typewriters.—No one tolerates pen work for letters written by clerks since it is known that typewriting is more legible, easier, faster, and cheaper, thus combining all four labor-saving elements. Many high salaried men have now learned that ease and speed make it well worth while to type such writing as they do with their own hands. If one writes at all, by as much as his time is more valuable than a \$10 clerk is the typewriter worth more for his personal use. The visible writers rapidly coming into use remove a serious objection, as each letter is in sight as written. By the touch system in growing use the operator never looks at the keys but strikes the right ones by touch, like a skilled pianist. (See *TYPEWRITER*.)

Fountain Pens are now as practical as dip pens, which are as absurd for the penman's constant tool as a muzzle-loading rifle for a modern soldier. Thousands have tried fountain pens and discarded them as failures, when they would have found them invaluable by observing these rules: (1) Select from a full line a pen exactly suiting the hand. More than 100 varieties of each first-class pen are regularly made. (2) Keep the gold pen bright by cleaning it often on a wet sponge. (3) Use a free-flowing standard ink, preferably filtered, and never mix inks or fill from a bottle open to air and dust. If clogged by poor or mixed inks or dirt, soak barrel and feeder thoroughly in water or wash out with alcohol. (4) To avoid top-heavy effect for sensitive hands, do not put cap on top of holder when writing.

Duplication.—Copying by hand was costly and untrustworthy. The copypress banished it. In turn this is largely superseded by the rubber roller copier, worked as easily as a clothes wringer and giving, with copying ink, five or more good copies if needed. The carbon sheet, usable with pencil or stiff, smooth-pointed pen, but best with typewriter, gives, with the one writing, 10 good copies on thin paper, or on cobweb paper 20 to 30. The best duplicator is the stencil cut on wax paper with typewriter and printed from a simple press up to several hundred copies, if needed, as permanent as other

printing. As the wax costs 8 cents a sheet, many have for temporary uses pans of composition on which anilin ink from pen or typewriter ribbon offsets. These use only common paper, are cheapest and quickest for temporary use if more than carbon copies are wanted, but anilin ink soon fades.

Card System.—This is easily greatest of labor-savers for literary and business use. With the modern library movement dating from 1876, its growth has been phenomenal and the saving effected more than money can measure. Instead of bound books, separate cards or sheets are used, on edge with frequently projecting guides, which enable one to find any item almost instantly. Matter may be added or removed at any point without recopying or disarrangement, so that the material is always up to date, and the plan is invaluable for every growing record, and has been adopted successfully for thousands of different applications. Its usefulness is diminished or destroyed unless the cards are cut to more exact height than common machines allow. A minute variation results in "bridging," that is, a low card between two higher ones is missed by the finger in turning. Equally important is it to have the best patterns of trays, supporting blocks, and locking rods to give the greatest possible speed in reference. Most patent devices for these purposes are useless. Libraries have by long experience found what gives best results. The international standard size card is 7.5 cm high, 12.5 wide, and is known as P or postal size. The United States Government prints its postcard, size K, and all its catalogue cards on this size, and the National and International Library and Bibliographic societies use this standard, which has in 25 years established itself beyond possibility of change. It is enough smaller than 3 x 5 inches, for which it is often mistaken by the inexpert, to make inch cards worthless in a standard index. They must be cut down to standard size or serious trouble will result.

This size is often found better to use in place of larger sheets for short bills, receipts, bank checks, etc., as they can be handled much quicker. The saving of space occupied seems trifling, but grows serious. Originally cards were over three times as large and were kept in a single row of covered boxes. The gain in number of cards stored on a given floor space was threefold when three rows of drawers replaced these boxes and 15-fold for the standard case 15 rows high; twofold more when cards were made half the thickness, twofold more when trays were made twice as long. Thus a library now stores 200 times as many cards on a given floor space, yet many are still embarrassed for lack of room. Single column trays with sides cut down to give more light and with label-holders in the pull have largely replaced the heavier two-column drawers. The best standard unit case is 2 to 3 pigeonholes wide and 15 high, each pigeonhole 9 x 29 cm and 50 cm deep, just holding 2 standard trays. Between the 6th and 7th rows of trays should be slides on which to rest drawers from pigeonholes too high or low to allow convenient reading. Short desk trays are 25 cm long with sides and partitions, if any, only 5 cm high, thus giving better light and easier handling than if full height of cards. All desk drawers should be full 9 cm

LITERARY LABOR-SAVERS

deep to hold these trays. All cards should have an 8 mm hole near the lower edge, in the middle. For private use locking rods needed in public indexes may be omitted, but the hole is often needed to tie cards together or for special uses. Rods are to prevent removal and loss, so that a notch in place of a hole is bad, as cards can be bent a little and readily removed without tearing. A pocket binder with eyelets opposite the card holes and a tie cord and bar is the handiest way to carry cards. The best card stock, weighing 200 grams to a square.metre, is as good as the older 300 or 400 gram stock which took twice the space. Heavier cards are needed only for guides. These with projecting tabs more than double usefulness. Cards as well as guides can be had with these tabs, affording immense possibilities of double, triple and quadruple classification by tab, card color, ink color, and number or heading. For lighter cards 133 gram stock, two-thirds the weight of the light standard, is best. With it 300 times as many cards can be put in a floor space as with the simplest combination of old outfitts. The 100 gram stock, which is ordinary five-pound commercial note-paper, is also used where space saving and cheapness are more important than ease of handling.

The largest standard card index is L size, for cards 25 cm high by 20 cm wide. The drawers are 21.5 wide and 28 cm high inside, and outside are 27.5 x 30 cm by 50 cm long. They have rods and blocks with sides cut away like the P size, but drawers are on extension slides so that they can be opened to their full length. The unit is four drawers high from the floor, the highest that can be readily consulted standing. The best low unit is two L drawers high with a P drawer and an extension slide and table top above, making a case 78 cm high, 32 cm wide and 50 cm long. This stands at the end of a desk as an extension, or better at right angles, so all cards may be read without rising from the chair. Heavy manila guides 27 cm high have tabs 4 cm wide projecting 1 cm higher. Another projection from the middle of the bottom runs in a groove in the drawer bottom and has a stout eyelet through which the locking rod runs, a necessity for so large cards. For these large sheets two folios not used in P size are needed. A manila envelop 20.5 x 25.5 cm, open at the top and right side, holds together stiffly enough to hold thin papers on edge. The long folio is of manila 20 cm wide, 51 cm long, folded with front 24 cm, back 27 cm high. In the top smaller subdivisions than indicated in the projecting tabs of the guides are written and closer classification of papers is maintained. Manila, white, blue, buff and other colors are used for these folios when more than one classification is wanted in the same series, for example, personal papers mingled with office or firm papers on the same subject. Thus papers belonging to a half-dozen different parties can be closely classified together by subjects without confusing ownership which is instantly recognized by the folio color. This L size index fits most magazines, pamphlets, letters and typewritten documents and is the best working unit for all papers too large for P trays. It is much preferable to filing on the long edge because papers may be read in the drawer with letterheads, titles of articles, etc., at the top in the best light, exactly like

library catalogs. The commercial vertical files, 12 in. wide, 10 in. high are slower in use because folios must be lifted out and opened before consultation. So many use objectionably large sheets with a line twice too long for easy reading that the larger file will be used for commercial purposes till business men learn the advantages of never using a sheet larger than 20 x 25 cm. For all other uses the L size is vastly better and when letters or papers on larger size come in they are quickly folded once and dropt into regular place.

Intermediate sizes are seldom needed. B or billet (10 x 15 cm), N or note (12.5 x 20 cm) are largely used, but a single size, D or double P (15 cm high by 12.5 cm wide), is best and has the great advantage that a single fold makes a card from this exactly fit standard P trays now universally used. The standard large sheet for card index stock is 50 x 60 cm and to save waste aliquot parts of this should always be chosen. Ninety-nine times out of one hundred P, D or L size will be better than any other, and odd sizes are more expensive and often wasteful when indexes are combined or rearranged. If other sizes must be had for special use, they should be chosen from this full series:

Sym- bol	Name	Size in cm.
V	Visiting card	5 x 7.5
H	Half P	6.25 x 7.5
I	Index	5 x 12.5
P	Postal	7.5 x 12.5
B	Billet	10 x 15
D	Double P	12.5 x 15
N	Note	12.5 x 20
3P		12.5 x 22.5
4P		15 x 25
L	Letter	20 x 25

Arrangement in any card system is either A to Z, like a dictionary, or 1, 2, 3, or classified, both numeric and classed plans having alphabetic indexes on P cards. The numeric system is best for correspondents writing many letters or for special contracts or other business distinct but not obviously classed under any subject or name. For this use the short numbers 1 to 9 or 99 should be reserved for the heaviest correspondence. The rest are assigned and indext as subjects arise, the folios being kept in 1, 2, 3 order. They can be filed or found much quicker than by any other than Arabic notation, which is the simplest known to the human mind. The numeric file is very bad in scattering by accidental order matter on allied subjects which ought to stand side by side. Every system should have an alphabetic supplement for miscellaneous correspondents who write few letters, since it is self-indexed and its few papers are put away and found again more quickly than if classified or numbered and indext. A great file of papers is like a library in miniature. Experience the world over has proved that while alphabetic and numeric systems are invaluable for many purposes, usefulness demands close classing as material grows. The best plan is to combine simplicity of numeric and utility of classed as in the 'Decimal Classification and Relative Index' used by most libraries. The simplest possible printed index of 20,000 headings tells instantly by what number to mark or to find any paper, for example, bees are marked 638. This means sixth class Useful Arts, third division Agriculture, eighth section Bees. Every paper

LITERARY LABOR-SAVERS

about bees is marked 638 and goes in the drawer in numeric order where it can instantly be found by the printed index. Twenty-five years' use in a score of countries has proved this numeric system, with its relativ index, a marvelous labor-saver. Classification is a necessity if all material on any given subject is to be readily found. The labor of making one's own classification is usually prohibitive if well done. By adopting the scheme in general use by libraries this labor is saved and numbers are in harmony with those of thousands of other catalogs and indexes in which the same number has the same meaning; for as was pointed out at a recent international congress, these numbers are an international language of perfectly definite meaning among all civilized nations, and also cheapest and quickest in application.

Individuals like libraries may often wisely separate "dead" from "live" material. Correspondence and topics no longer often consulted are transferred to duplicate drawers, which for storage may be of cheaper construction. Working drawers and trays near the desk will thus be filled with matter oftenest used, while that removed is not tied in bundles or packt in boxes, but is kept best and most cheaply in P and L drawers, in a single series, so that matter removed at different times is all found in its exact numeric or alphabetic order regardless of date of removal. The index entry shows by an underscore topics removed to storage, so that no time is lost in double reference. This system has had a marvelous growth as people learn its economy of time and space. Formerly papers were folded, endorsed and tied in bundles. Flat filing in cabinets, minutely self-indexed without labeling, drove out this costly system. Vertical filing, like a library catalog, is in turn rapidly driving out flat filing cabinets. The loose leaf system is only a variation of the card index of which the essential is indefinite intercalation. Instead of standing on edge in drawers, loose leaves are put in a Unimatic or some other binder by a device which holds them like a book, opening flat but allowing leaves to be added or removed at any point almost instantly. For certain desk uses this is preferable to trays, but the tendency grows to put business ledgers, bank records and everything else in regular trays. The fear of losing detached pieces proves practically groundless and the saving over books is very large.

Colors.—These may be given mnemonic values in binding, paper or ink. Languages, not subjects, should guide in bindings if books are arranged, as almost universally, by subjects, for variety of color is important in finding and replacing books quickly. The language scheme used for 20 years by some libraries is:

1. American, light brown
2. English, dark brown
3. German, black
39. Minor Teutonic, dark blue *
4. French, red.
5. Italian, maroon.
6. Spanish, olive.
7. Latin, light green.
8. Greek, dark green.
91. Minor Aryan, light blue.
92. Semitic, yellow.
- 93-99. Hamitic, etc., light drab.

Colors beginning with the same letter as the subject are easier remembered, but should not be chosen if a distinctly better color is available.

Libraries use blue for bibliography, canary for criticism, green for biography. Slips are often arranged by days or months:

Sunday	sage green	Thursday	turquoise
Monday	melon		or manila
Tuesday	terra-cotta	Friday	fawn
Wednesday	white	Saturday	straw
January	white	July	blue
February	fawn	August	apple green
March	melon	September	straw
April	azure	October	orange
May	manila	November	nile green
June	jonquil	December	dove

The checklist below of paper colors for 26 letters omits most of those too dark to be written on or often confused. The second colors named often confuse with others first in the list elsewhere and so are seldom used. Letters with no available color are assigned the best unused, so as to give colors to all 26 letters if needed:

A	azure, apple green, amber
B	blue, buff, brown
C	canary, cherry, carmine, cream, café-au-lait
D	dove, drab
E	ecru
F	fawn
G	green, gold, gray, granite
H	heliotrope, hazel
I	ivory, indigo
J	jacqueminot, jonquil
K	corn
L	lilac, lavender, lemon
M	melon, mauve, marigold, manila
N	nile green
O	orange, old gold, olive
P	pink, primrose, pearl gray, purple
Q	Quaker drab
R	red, rose, robin egg
S	sage, straw, salmon, sky blue, steel
T	terra-cotta, turquoise, tea, tan
U	ultramarine, buff
V	violet, mauve
W	white
X	granite
Y	yellow
Z	zenith, manila

The favorite distinct colors to write on are white, buff, blue, canary, green, cream, manila. Melon or salmon soils worst from handling. As cards must be of uniform size to fit trays and drawers, the distinction of various circulars and blanks often made by shape is best made by color.

Ink Colors.—The best colors in order are: Black, red, blue, green; and least permanent, violet or lilac. Colors are used chiefly for figures or other short entries or for checking lists. Two, three or four pens or pencils can be carried between the fingers so that a check mark may be made instantly in either of four colors. Red is used for receipts, returns, income, renewals; blue for the reverse, payments, outgo, issues; green for gain; lilac for loss. Special meanings are assigned to check marks for each case and should always be written at the beginning of the list for future reference. Different colored inks or pencils are often assigned to different people working over the same lists so that color shows who made each mark. Where classification may change, color is better in ink than in paper as recopying can be saved by underscoring the first words in the new color which supersedes the old.

Exact Reference.—In indexes and other exact work indicate by superior figures the particular ninth of page or column in which the passage referred to begins; for example, 5:34⁸ means vol. 5, p. 34, beginning in third ninth of the page (about one-third the way down). Of superior figures, odd numbers 1, 5 and 9 denote top,

LITERARY PROPERTY — LITERATURE

middle and bottom of pages; 3 and 7, points half way between top and middle or middle and bottom, while even numbers are mere modifiers of these positions, 2 denoting a point a little below the top, 8 a point a little above the bottom; 4 and 6, points just above and below the middle. If there are several columns on a page, use two superior figures, the first denoting column and the second position in the column; for example, 7:89th means vol. 7, p. 89, beginning in the third ninth of column 1 and ending near the bottom (in the eighth ninth) of column 2. In condensed matter use the library date system (1) Day of week, (2) day of month, (3) month, (4) year:

Months						Days		
J	A	P	J	O	S ^u	T ^h		
F	Ap	My	Jl	N	M	F		
Mr	Je	S	G	D	Tu	St		
					W			

For Wed. 9 Sept. 1885, write W 9 S 85.

Numbers for months are dangerous. As usage is about equally divided, no one can tell whether 6-7 means July 6 or June 7. The L. B. dates above are exact and average fewer marks.

Numbers.—Use only Arabic numerals and letters and avoid the clumsy and easily misread Roman numerals; for example, Vol. 88, not Vol. LXXXVIII.

Newspaper Clippings.—These are almost useless unless closely classified. Plain manilla sheets 20 x 25 cm are better than any patent scrap-book. They are clasp like other papers with subject number on left upper corner and are kept laced in binders or much better in L drawers like thin pamphlets, thus bringing clippings, circulars, letters and notes on each minute topic all together in one folio.

Metric System.—John Quincy Adams reported to Congress that if metric weights and measures could be generally used they would be a greater labor-saver to the human race than steam. Since then nearly all civilized nations have adopted these measures, and America and England are both nearing such adoption. The international decimal system, agreeing perfectly with our arithmetic, stands near the head as a labor-saver. Computation showed that a single railroad could save \$50,000 a year in clerical labor by its use.

Colon Forenames.—In library catalogs where space is important, the most common full names are indicated by initials followed by a colon or double period, thus C:H:Smith is known to be Charles Henry Smith, while C. H. Smith may have any names beginning with C or H. With no extra space or cost the full name is given accurately by adopting C: A. Cutter's library list below:

A: Augustus.	A.: Anna.
B: Benjamin.	B.: Beatrice.
C: Charles.	C.: Charlotte.
D: David.	D.: Delia.
E: Edward.	E.: Elizabeth.
F: Frederick.	F.: Fanny.
G: George.	G.: Grace.
H: Henry.	H.: Helen.
I: Isaac.	I.: Isabella.
J: John.	J.: Jane.
K: Karl.	K.: Kate.
L: Lewis.	L.: Louisa.
M: Mark.	M.: Mary.
N: Nicholas.	N.: Nancy.
O: Otto.	O.: Olivia.
P: Peter.	P.: Pauline.
R: Richard.	R.: Rebecca.
S: Samuel.	S.: Sarah.

T: Thomas.	T.: Theresa.
U: Ulrich.	U.: Ursula.
V: Victor.	V.: Victoria.
W: William.	W.: Wilhelmina.
Z: Zenobia.	

Nine tenths of matter usually kept flat in drawers is better kept on edge in L size vertical files which are handiest and cheapest except for papers in constant use in open pigeonholes; cards in P trays and books and pamphlets on shelves. The best library shelf is 75 cm long, 20 cm deep and 25.5 high, thus taking all books up to octavo, 25 cm. Cases should be seven or eight shelves high with 15 or 20 cm ledge, if wisht, above the three lower shelves. The best pamphlet case is a plain wood box covered with marble paper, open only on the back. This is handier and more durable than costly patent boxes. Shelves, pigeonholes and blanks should all be read from top to bottom and from left to right like the columns of a newspaper, never jumping over the upright.

The most practical, cheapest and oftenest needed labor-saving is to use the fewest words and marks that will convey meaning readily and accurately. For definite lists and suggestions in economy of language, see NOTEHAND.

MELVILLE DEWEY,
Director New York State Library.

Literary Property. See COPYRIGHT.

Literature, Canadian. comprises in its widest acceptation, those phases of French and English literature, which, with an indigenous assimilation, have developed during and since the period of Canadian colonization and settlement. (See CANADA.) In its earliest stages it consists of the recitals of discovery and exploration of French explorers and Catholic missionaries, and the transported and localized traditions of the first Breton and Norman peasant immigrants, amassed and crystallized during successive generations, until they have reached the present century in a collection of literature of unsurpassed interest. After Canada became a British possession, by the Treaty of Paris in 1763, alongside of the continued development of French-Canadian literature, which, naturally was confined to settlers of French origin, chiefly in the Province of Quebec or Lower Canada, there arose an Anglo-Canadian literature fostered by the early British settlers, shortly afterward reinforced by the advent of United Empire loyalists, who at the close of the Revolutionary War, left the United States, and settled principally in the maritime provinces of New Brunswick and Nova Scotia, and in Ontario or Upper Canada. During the first half of the 19th century these growing branches of Canadian literature followed their divergent yet parallel courses, until after 1841, with the union of Upper and Lower Canada, and later with the confederation of the provinces, they found a common and sympathetic bond in the patriotic expression in both languages of the newly awakened sentiment of nationality, which has become an important factor in the political and general life of the Dominion. Canadian literature in all its branches includes authors, not only of native birth, but also numerous British, French, and other writers, who have settled or resided in the Dominion, and imbued by sentiments and interests wholly Canadian, have enriched its annals with their contributions.

LITERATURE

The earliest writings on Canada, dating from 1599, are those of the explorer Champlain, which frequently republished, are collected in the six volumes' issue edited by Laverdière and published at Quebec in 1870. Other early productions are Lescarbot's 'Histoire de la Nouvelle France' (1609), and 'Les Muses de la Nouvelle France'; La Pothérie, 'Histoire de l'Amérique Septentrionale depuis 1534 jusqu'à 1701' (4 vols. 1722); Lafitau, 'Mœurs des Sauvages amérindiens' (1724); Charlevoix, 'Histoire et Description générale de la Nouvelle France' (3 vols. 1744); while a mass of interesting material is contained in 'Rélations des Jésuites' which can be consulted in the collection of 71 volumes, edited by Thwaites, with an English translation, and published at Cleveland, Ohio (1896-1901).

Among the first works of native authorship are Bibaud 'Histoire du Canada sous la Domination française' (1837) and 'Histoire du Canada sous la Domination anglaise' (1844); Garneau, 'Histoire du Canada' (1845-52). These were followed by Casgrain, 'Légendes canadiennes' (1861) and 'Biographies canadiennes' (1885); Boucher de la Bruère, 'Le Canada sous la Domination anglaise—Analyse historique' (1863); Tanguay, 'Dictionnaire généalogique des Familles canadiennes depuis la Fondation de la Colonie jusqu'à nos Jours'; and the celebrated work of the prolific Sulte, 'Histoire des Canadiens français' (8 vols. 1882-4). To these French-Canadian historical writers may be added L. O. David 'Les deux Papineau' etc.; P. De Cazes, De Celles, De Montigny, N. E. Dionne, G. A. Drolet, J. E. Roy, J. B. A. Ferland, L. Turcotte, A. H. Gosselin, etc.

In the 'Chansons populaires du Canada' and the 'Cantiques populaires du Canada-français' edited with music, Ernest Gagnon, organist and composer, has preserved the Canadianized songs of early Breton and Norman importation and the earlier native effusions, while an excellent general view of French-Canadian poetry by the versatile B. Sulte, himself a popular poet, is 'La Poésie française au Canada' (1881). Among the better known French-Canadian poets are L. H. Fréchette, 'Les Fleurs boréales' and 'Les Oiseaux de Niège'; O. Crémazie, 'Le Drapeau de Carillon,' etc.; J. (Mrs.) Dandurand, 'Les Contes de Noël,' etc.; J. L. Archambault, 'Jacques Cartier,' a historical drama; L. P. Lemay, 'Essais poétiques,' etc.; N. Legendre, 'Echos de Québec,' etc.; L. J. C. Fiset, A. B. Routhier, 'Les Echos,' etc.

French-Canadian fiction is represented by P. De Gaspé, 'Les anciens Canadiens' (1863); J. Marmette, 'L'Intendant Bigot' (1872), etc.; H. Beaugrand, 'Jeanne la fileuse'; N. Bourassa, 'Jacques et Marie,' an Acadian romance, etc.; P. J. O. Chauveau, L. P. Lemay, C. A. N. Gagnon, etc.

Anglo-Canadian literature commences with the account by Samuel Hearne, 'A Journey from Prince of Wales's Fort in Hudson's Bay to the Northwest' (1795), being the recital of a pedestrian trading journey of 1,300 miles to the Great Slave Lake. This was followed by A. Mackenzie, 'Voyages on the River Saint Lawrence and Through the Continent of North America to the Frozen and Pacific Oceans' (1801); J. Bouchette, 'A Description of the Canadas' (1815-32); W. Smith, 'History of

Canada' (1815), and J. Howe (a Nova-Scotian), 'Western and Eastern Rambles.' One of the first distinctive native authors was Judge T. C. Haliburton of Nova Scotia who, in 1835, with 'The Clockmaker, or Sayings and Doings of Sam Slick of Slickville,' originated the dialect humor which is generally looked upon as a United States product. Judge Haliburton was the author also of a 'History of Nova Scotia,' while Francis Parkman (1823-93), the American historian whose researches occupied more than forty years, in his monumental standard works 'Pioneers of France in the New World' (1865); 'The Jesuits in North America' (1867); 'La Salle and the Discovery of the Great West' (1869); 'The Old Regime in Canada' (1874); 'Count Frontenac and New France under Louis XIV.' (1877); 'Montcalm and Wolfe' (1884); 'A Half-Century of Conflict' (1892); was the first to lay the Rélations des Jésuites under contribution and do for Canada what Prescott did for Mexico. Among a long list of Canadian historians are G. M. Adam, 'The Canadian Northwest; its History and Troubles' (1883); J. S. Archibald, 'The Relations of the Two Races in Lower Canada'; A. Begg, 'History of the Northwest' (1894-5); G. Bryce, 'History of the Canadian People' (1887), etc.; J. G. Bourinot, 'Canada under British Rule' (1900), etc.; R. Christie, 'History of Lower Canada' (6 vols. 1849-55); W. Canniff, 'Canadian Nationality' (1875), etc.; J. B. Crozier, 'Civilization and Progress' (1885); J. C. Dent, 'The Story of the Upper Canada Rebellion' (2 vols. 1885-6), etc.; J. Hannay, 'History of Acadia' (1879); O. A. Howland, 'The 400th Year of Canadian History,' etc.; W. Kingsford, 'History of Canada' (10 vols. 1887-97); J. M. McMullen, 'History of Canada' (1855); E. Richard, 'Acadia' (2 vols. 1895); H. Scadding, 'Toronto: Past and Present' (1884); C. G. D. Roberts, 'History of Canada' (1897); W. H. Withrow, 'History of Canada' (1880), etc. Chief among modern historians native or resident is Professor Goldwin Smith (q.v.), living in Toronto since 1871, whose 'Canada and the Canadian Question' (1891) is a minor work in the long list of his valuable publications of world-wide interest.

The list of Anglo-Canadian poetry is a long and worthy one, and among its most notable exponents are Bliss Carman and Sir H. Gilbert Parker (q.v.); I. V. Crawford, 'The Master Builder,' 'The Axe of the Pioneer,' etc.; G. F. Cameron, 'What Reck we of the Creeds of Men,' etc.; A. Lampman, 'Among the Millet' etc.; J. W. Bengough, the versatile poet, humorist, and cartoonist, one of the most tender and graceful of Canadian elegiac poets; C. G. D. Roberts, 'Poems of Wild Life,' 'Canadians of Old,' etc.; Wm. Kirby, 'The U. E.,' 'Canadian Idylls,' etc.; J. A. Allen; D. Anderson, 'Lays of Canada'; J. G. Ascher, 'Voices from the Hearth' (1863); C. L. Betts, 'Songs from Berger,' etc.; J. (Mrs.) Blewett; J. H. Brown; W. W. Campbell, 'The Mother,' etc.; J. (Miss) Carnochan, 'Has Canada a History,' etc.; M. R. (Miss) Charlton; C. A. (Miss) Frazer; A. R. (Mrs.) Christie, Annie Rothwell, poet and novelist; G. G. Currie, 'How I Once Felt: Songs of Love and Travel'; S. A. (Mrs.) Curzon, 'Laura Secord, the Heroine of 1812,' a drama; E. H. Dewart, 'Songs of Life,' 'Selections from Canadian Poets'; A. G. Doughty; W. H. Drum-

LITHARGE — LITHIUM

mond, 'The Papineau Gun'; 'Johnnie Courteau and other poems'; A. W. H. Eaton, 'Acadian Legends and Lyrics'; C. (Miss) Fairbanks; J. K. Foran, 'Poems and Canadian Lyrics'; C. S. Goodhue; J. M. Harper; S. F. (Mrs.) Harrison, 'Pine, Rose, and Fleur de Lis'; C. Heavysege, 'Saul'; S. M. A. (Mrs.) Hensley, 'A Woman's Love Letters' (1895); S. Hunter-Duvar; J. Inrie; E. P. (Miss) Johnson; R. K. Kerningham, 'Men of the Northern Zone,' 'Canada First,' etc.; W. D. Lighthall, poet and novelist, 'Songs of the Great Dominion,' etc.; A. J. Lockhart; C. Mair; G. Martin, 'Marguerite, or the Isle of Demons' (1887); S. (Mrs.) Moodie, sister of Agnes Strickland; M. (Miss) Morgan; A. Muir, 'Canada,' 'The Old Union Jack,' 'Canada, Land of the Maple Tree,' 'Canada Forever,' etc.; G. Murray, 'How Canada was Saved,' etc.; E. MacColl; D. McCaig, 'Milestone Moods and Memories'; W. McLennan, 'Songs of Old Canada,' etc.; T. O'Hagan, poet, critic and essayist, 'Songs of the Settlement,' 'Canadian Essays, etc.'; T. H. Rand, the Canadian Browning, 'At Minas Basin and other poems'; J. J. Roche, 'Songs and Satires'; C. Ryan, 'Songs of a Wanderer,' etc.; F. G. Scott; A. M. Sinclair; E. H. Stafford; B. Stratton; J. S. Thompson, 'Estabelle and other Verse'; etc.

Although of native birth and claimed as a Canadian writer, Grant Allen, novelist and naturalist, is typically Anglo-Saxon in the universality of his works, fictional and otherwise. The greatest writer of fiction Canada has produced is Sir Gilbert Parker (q.v.), 'the literary discoverer of the Northwest,' who in 'Pierre and His People' (1892); 'When Valmont came to Pontiac' (1895), 'The Seats of the Mighty' (1896), and 'The Right of Way' (1901), has anglicized French-Canadian themes with a vigor and interest of world-wide celebrity. Even when he has traveled foreign for his subjects, their nationality curiously exhibits a mixed colonial influence of Canadian origin as in 'The Battle of the Strong,' the scene of which is laid in 'Little Known Normandy—the Island of Jersey,' whence came the ancestors of many early Canadian colonists, represented in the Canadian literary world at this day by, among other descendants, J. E. Le Rossignol, noted for his philosophical and other essays, and by W. D. Le Sueur, whose literary and critical essays on 'Matthew Arnold,' 'Bernardin de St. Pierre,' 'Saint-Beuve,' etc., are of a high order. Among other writers of native fiction are G. M. Adam with A. E. (Miss) Wetherald in 'An Algonquin Maiden'; K. M. (Miss) Barry, numerous novels, including 'Honor Edgeworth, Ottawa's Present Tense,' 'The Doctor's Daughter, a sketch of Canadian social life and character'; R. (Miss) Barry; M. (Mrs.) Catherton; P. Cox, artist and author of 'The Brownie Books,' etc.; J. Croil 'Dundas: a sketch of Canadian history'; S. J. (Mrs.) Cotes, 'The American Girl in London'; F. B. Crofton, 'The Major's Big Talk Stories'; E. A. Cruikshank, military subjects; A. Davies, 'Canadian short stories'; L. (Miss) Dougall, 'Madonna of a Day' (1896); E. L. (Mrs.) Estey; J. Galt, 'Laurie Todd or the Settlers in the Wood' (1830); J. B. (Mrs.) Hammond; S. F. (Mrs.) Harrison; H. E. (Mrs.) Hayes (Mary Markwell); T. S. Jarvis, 'Doctor Perdue,' 'The

Ascent of Life,' etc.; A. R. (Mrs.) Logan 'Children of the Hearth'; B. L. (Miss) Macdonell, 'Tales of the Soil,' etc.; J. N. (Miss) McIlwraith (Jean Forsyth); W. McLennan; E. J. (Miss) McManus; G. A. (Mrs.) Newhall; J. M. Oxley; J. Richardson, 'Wacousta, or the Prophecy' (1833); J. A. Phillips, 'Out of the Snow,' etc.; R. Pocock, 'Tales of a Western Life'; M. A. (Mrs.) and A. T. (Miss) Sadlier; M. M. (Miss) Saunders, 'Daisy' (1892), 'Beautiful Joe' (1894); E. E. Shepard; E. W. Thompson; H. B. Willson; E. R. Young; etc.

The list of notable Canadian essayists and miscellaneous writers in all branches of theology, philosophy and science is too long to be enumerated here, but of purely literary critics and essayists besides W. D. Le Sueur already mentioned may be cited W. J. Alexander, R. G. Haliburton, T. A. Haultain, J. C. Hopkins, N. F. Davin, S. E. Dawson, A. M. MacMechan, T. O'Hagan, L. J. A. Papineau, T. Watson, etc., while in the collected and published speeches of J. Howe, Sir W. Laurier, Alexander Mackenzie, Sir John Macdonald, Sir Charles Tupper, etc., Canada has a rich anthology of oratorical literature.

CHARLES LEONARD STUART, B.A.,
Editorial Staff, 'Encyclopedia Americana.'

Litharge, lith'arj (Greek, silver-stone), the fused oxide of lead as got in the cupellation of silver and gold. See LEAD.

Lithia, in chemistry, oxide of lithium (q.v.).

Lithia Mica. See LEPIDOLITE.

Lithic Acid. See URIC ACID.

Lith'ium, a name applied to an alkali discovered in 1817. It was derived from the Greek *lithos* (a stone), in allusion to the existence of the alkali in a stony mineral. Lithia has since been detected in spodumene, lepidolite, triphyllite, amblygonite, tourmaline, meteoric stones, mineral waters, coffee, tea, blood, milk, etc. A process for procuring it is the following: One part of petalite or spodumene in fine powder, is mixed intimately with two parts of fluor-spar, and the mixture is heated with three or four times its weight of sulphuric acid, as long as any acid vapors are disengaged. The silica of the mineral is attacked by hydrofluoric acid, and dissipated in the form of fluosilicic acid gas, while the alumina and lithia unite with sulphuric acid. After dissolving these salts in water, the solution is boiled with pure ammonia to precipitate the alumina; is filtered, evaporated to dryness, and then heated to redness to expel the sulphate of ammonium. The residue is pure sulphate of lithium. Its color is white; it is not deliquescent, but absorbs carbonic acid from the air; it is soluble in water; it is acrid and caustic, and acts on colors like the other alkalies; heated with platinum it corrodes it rapidly. It combines with the different acids, and forms crystallizable salts with them. The phosphate and carbonate are sparingly soluble; the chloride is deliquescent and soluble in alcohol, and this solution burns with a red flame. Unlike the other alkalies it cannot be reduced from its car-

LITHOGRAPHIC CRAYON — LITHOGRAPHY

bonate by carbon, but it requires the action of a galvanic battery. The compound employed is the chloride, which, while in a state of fusion, is acted on by the battery. Small globules collect round the negative pole, and these are removed and cooled under petroleum. It is the lightest of metals. It has a bright silver-white metallic lustre, melts at 356° F., and can be welded at ordinary temperatures. It is rather harder than potassium, can be drawn into a wire, but has a low degree of tenacity. Exposed to the air it tarnishes, but it combines with oxygen less rapidly than either sodium or potassium. It decomposes water, and when heated in oxygen, chlorine, and other gases, burns with a brilliant light.

Compounds of lithium are used in pyrotechny on account of the splendid red color they impart to flame. In medicine the carbonate is employed especially as a solvent for uric acid, to prevent the formation of calculi and to remove it from the system in gout. Effervescent lithia water is sometimes used in place of soda or potash water. Citrate of lithia is also employed. It is a white, soluble, crystalline salt, prepared by dissolving the carbonate of lithium in citric acid. Its therapeutic properties are similar to those of the carbonate.

Lithograph'ic Crayon. See LITHOGRAPHY.

Lithographic Stone. See LITHOGRAPHY.

Lithography (*Greek, lithos*, stone and *graphein* (to write), may be divided into two distinct branches—lithography proper, the art of writing, drawing or engraving on stone, and chemical or surface printing from stone or metal, by means of which such writings, drawings or engravings are multiplied, in a manner differing essentially from letter-press or relief printing on the one hand and steel and copper plate or intaglio printing on the other. Lithographic printing is based upon the chemical principle of antagonism of grease and water and upon the porous nature of the printing surface. By virtue of this property, a drawing made upon such surface with unctuous ink or crayon will adhere to it so firmly that its eradication can only be effected chemically by means of strong acids or mechanically by entirely removing the surface with the design. The parts of the surface containing the drawing or design will accept and hold grease or ink, and those parts of the surface free from design will receive and retain water to the evaporating point. Thus if a roller covered with fatty printing ink is passed over the printing surface previously moistened, the ink will attach itself only to the parts constituting the design and will be repelled by the moisture covering the remaining part of the surface, in consequence of which the design only will appear in the impression.

History.—Aloys Senefelder is generally conceded to be the inventor of lithography, although in certain quarters claims have been put forth in favor of Simon Schmidt of Germany. The latter's claims, however, are without much basis. As early as 1788 he printed from stone, but his idea bore no relation to Senefelder's discovery, ten years later, of chemical or surface printing. Schmidt merely substituted stone for metal in relief printing, which bears no resemblance whatever to the process of lithography. Sene-

felder was born at Prague in 1771 and at an early age removed to Munich, where his father was employed as an actor at the Theatre Royal. The future inventor had a bent for his father's calling, but parental opposition finally induced him to enter the university at Ingolstadt as a law student. His college days were shortened, however, for soon after his entrance, his father died, thus throwing the youth upon his own resources. His attempts at supporting himself met with indifferent success. First as an actor and then as a playwright, he proved a failure, but this very circumstance had much to do with his ultimate discovery of chemical printing. His inability to get his work as a playwright published in the usual way bestirred him to devise some means of doing it himself. Thus he set about to become familiar with the printing art, which culminated in the purchase of a small press. Too poor, however, to pay for the engraving of his compositions, he next turned his attention to etching on copper. His inexperience in forming the reversed characters on the plate led to frequent errors, and not being familiar with the "stopping out" solution used by etchers in rectifying mistakes, he succeeded in devising one of his own. The ingredients he used were those nearest at hand—the wax with which he coated the plates previous to etching, the soap with which he washed the ink from the plates and the lampblack which he used in preparing his ink for printing. Thus accidentally he discovered the composition which forms the basis of all crayons and lithographic drawing inks. The labor attached to grinding and repolishing the copper plates led him to experiment with a fine piece of Kellheim stone, originally purchased to grind his ink with. After treating this in precisely the same way as copper plates, he succeeded in getting some fairly good impressions. Subsequently it occurred to him to reverse the etching process by writing on the stone with the "stopping out" composition and biting down the surface with aqua fortis. This brought out the character in relief, which he inked in and printed in the manner of type. Further experiments led to the discovery that relieving the characters was altogether unnecessary and that the simple process of writing on the stone with his composition of wax, soap and lampblack produced the same results. This was in the year 1798 but it was not until eight years later that the inventor succeeded in establishing himself as a lithographic printer in Munich. This city thus became the centre of the art, and three years thereafter no fewer than seven separate concerns were established, as well as a number of private presses. Senefelder died in 1834, and since then there has been little or no change in the method he laid down, the inventor having exhausted almost its entire possibilities. While to Senefelder is due the lion's share of praise, many others of the early lithographers are entitled to great credit, they having done much to develop and foster the craft. Piloy in 1808 published 432 copies of the old masters, and in 1815 reproductions from the Munich gallery. His partner, Lochie, was also conspicuous in the early development of lithography, as well as Count Lasserie, who introduced the art in Paris. It fell to Godfrey Engelmann to

LITHOGRAPHY

found the first permanent establishment in Paris. This was in 1816. In 1837 he was granted letters-patent on the invention of chromolithography. The first house in Berlin was established in 1834 by Franz Hanfstängel, and in London in 1822, by Hullmandel, a pupil of Engelmann of Paris. Senefelder himself attempted to establish himself in London, but failed, owing to some difficulty with his partner, André, of Offenbach.

Lithography as an art reached its climax in Paris during the reign of Louis Philippe. Among the masters who distinguished themselves were the satirists Daumier, Grandville, Travies and Gavarni, Deveria, Delacroix, Joffannot and Gigoux, the delineators of romantic literature; Charlet and Raffet, who found material in the glorification of Napoleon's career. Other painter-lithographers of the day were Géricault, Richard Park Bonington, James Duffield Harding, Eugene Isabey, Alexandre Calame and Julien, whose "Etudes en Deux Crayons" made his famous. Since the introduction of the power press and the consequent development of the lithographic industry as a commercial factor, the medium of lithography has found less favor as a mode of artistic expression, but efforts are now being made to create renewed interest in an art so true in its reproduction of the artist's pencil. Commercially it has grown to be one of the most important branches of the printer's craft, as evidenced by the fact that in the United States alone, according to the census of 1900, the capital invested was \$22,676,142, and employment was given to almost 14,000 people.

Materials.—The stone used for purposes of lithography is a compact, homogeneous limestone of porous texture, known as "lithographic stone." It varies in color from a light cream, dull yellow, drab or gray to darker shades of the same colors, the best being found among the light gray varieties. The dark blue-gray or French stone is very fine in texture, but is not favored generally by either the artist or the transferrier, as its color does not contrast sufficiently with that of the design to enable the manipulator to gauge his work as well as on a light gray stone. Lithographic stone is quarried chiefly at Solenhofen, Germany, and while similar stone has been found in England, France and America, none possess the quality of the Solenhofen product. It is sawn at the quarries into slabs of from 3 to 4 inches in thickness, varying in size from 6 x 8 inches to 44 x 64 inches, and is sold by weight. The cost, as compared to its area, increases, not simply arithmetically, in proportion and weight, but in geometrical progression, as in the case of diamonds and other precious stones. Thus a stone measuring 3 x 4 inches, weighing 20 pounds, costs 1½c per pound, and a stone measuring 44 x 64 inches, weighing 1,200 pounds, may cost as much as 40c per pound. The common occurrence of hidden flaws in stones, leading to fracture under pressure when printing therefrom, and the difficulty of securing large stones without blemishes, such as chalk spots or veins, has been a source of constant trouble. For this reason, as well as owing to the expense incurred in handling and storing the cumbersome stone, a substitute embodying the same

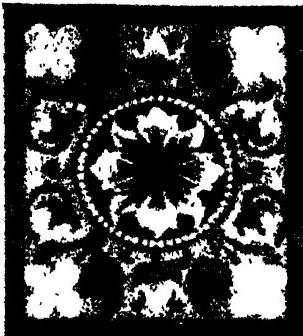

properties has been the desideratum of lithographers almost since the invention of surface printing. Zinc has been in use for 50 years or more, and while it possesses the necessary qualities to a limited extent, it has never proved useful for any but the most ordinary grades of work. Other metals and materials, as well as artificial stones have been tried, but none were found suitable, until with the introduction of aluminum as a trade article, experiments with that metal were made by John Mullaly, of New York, and later by Otto C. Strecker, of Mainz, Germany, resulting in the almost universal adoption of this metal as a perfect substitute for the lithographic stone. Designs can be removed from either stone or metal plates and their surfaces prepared for the reception of new designs. A stone 4 inches thick or an aluminum plate 29/1000 of an inch thick can thus be used approximately 200 times. Lithographic crayon is composed of beeswax, shellac, tallow, mastic turpentine, soap and lampblack. It is made in several degrees of hardness. For crayon work the surface of the stone is always grained by means of grinding with clean, sharp sand and water between two slabs of stone. Lithographic ink adapted for pen work on stone contains the same ingredients as used for the crayon with a larger quantity of the soap, in order to make it soluble in water. The ink is furnished in sticks and rubbed over a plate or saucer and then gradually dissolved with water or turpentine until it becomes fluid. Gum arabic and acids are important factors in lithography; in fact, Senefelder's original invention would have proved of little practical value had he not also discovered their uses in reinforcing the qualities of the stone. When a drawing is completed on stone, its surface is treated with a solution of gum arabic and nitric acid, effecting a chemical change in its nature where it is not protected by the grease or ink of the drawing. The carbon is freed and a nitrate deposited in the form of a full grained pellicle, the pores of which retain the gummed water, thus creating a surface impermeable to grease. Furthermore, the drawn parts are rendered insoluble in water by decomposing the alkali contained in the soap—one of the component parts of lithographic crayon or ink. The object of this etching is not to elevate the drawing—the relief, if any is obtained, being hardly perceptible, and although it tends to make the impression cleaner and sharper, is not absolutely necessary.

Process.—After the stone is etched, it is washed successively with water and turpentine. When wiped clean, the surface at first glance appears to be perfectly blank, but on closer inspection shows a faint suggestion of the design in white on the face of the stone. After being repeatedly moistened and rolled in with printing ink, the design reappears and accepts the ink. It is then covered with a weak solution of gum arabic and is ready for printing. A drawing on stone is necessarily reversed and it requires considerable experience on the part of the artist to obtain proficiency in thus rendering a reverse facsimile of the original. In the hands of an experienced and capable artist no reproductive art can offer greater possibilities than that of crayon drawing on a grained stone.

LITHOGRAPHY

It permits greater freedom as compared with steel, copper plate or wood engraving, inasmuch as technique is less important in lithographic crayon work than true artistic ability, while an infinite variety of tones, from the most delicate shade to rich, deep black, lies within its possibilities. Somewhat more mechanical is the pen stipple manner, which, as its name implies, consists of drawing with small dots, the relative values of shading being determined by the varying density of the dots. This manner is employed mainly in chromo-lithography, its chief recommendation being the clean, sharp, solid nature of the work, and it is therefore particularly adapted to large editions of printing. The greatest achievement of lithography undoubtedly centres in the reproduction of oil paintings and aquarelles, commonly known as chromo-lithography. Either the crayon or pen stipple manner alone or both together, in connection with other manners, such as "rub tints," "asphalt tints," etc., are brought into the work. Its most simple form is the tint used for crayon drawings; its highest, the reproduction in colors of an oil or water color painting, requiring a series of drawings on separate stones—one for each of the colors necessary to produce the facsimile. The important feature is to obtain a perfect register of the various printings, as any deviation of the correlation of the colors will tend to produce entirely foreign effects. One of the methods whereby this is accomplished is making a key plate. An accurate detailed tracing is made of the original by means of an engraving-needle, scratching the surface of a sheet of transparent gelatine or celluloid, indicating the boundaries of even the most minute patches of color. The engraved lines are charged with lithographic ink and then transmitted to stone by pressure. After the register marks (usually in the shape of crossed lines) have been put in the margins of the key plate, the stone is etched and rolled up with printing ink, and impressions corresponding to the number of colors or printings to be employed are made therefrom. The impressions are powdered with finely ground dry powder (usually Venetian red), which adheres only to the outline of the design, and then transmitted by pressure to the surface of clean stones. These so-called "offsets" of the key serve as a guide for the artist in making his color plates. In cases where no key of the original is made, offsets from the drawing of the black supplied with the necessary register marks answer the same purpose. The number of colors necessary to produce a given result varies largely, according to the nature of the original to be reproduced, ranging for commercial purposes from three to fifteen, although where especially fine results are desired, 20 or more colors may be required. The stone-engraving manner—used extensively for commercial stationery in imitation of steel engraving—is based on the same principle, although the mode of procedure differs in every respect. For this purpose the stone is polished, its whole surface is first prepared or etched with gum-water acid and covered with a dark ground consisting of lampblack in solution with gum-water or albumen. Into this ground the design is engraved or scratched with an engraving-needle or a diamond. Then linseed

oil is poured over the whole, which is absorbed by the stone where the needle has laid it bare. The ground is washed off, the surface moistened and printing ink rubbed in with a tampon or dauber, the ink adhering only to the lines of the design, by reason of the oil which they have absorbed.

Photography.—Since its invention, photography has been more or less allied to the lithographic art. Its most common application is the process called "photo-lithography," by means of which pen drawings are transferred to lithographic stone at comparatively small expense. The half-tone or Meisenbach process has also been advantageously applied—particularly in chromo-lithography—in furnishing a basis for the several color plates, in place of the key, usually assuring a more faithful reproduction of the original than would be possible otherwise. One of the earliest photo-lithographic processes in use is that of Lemercier, patented in 1852, which is based on the sensitive property of asphaltum, discovered by Niepce in 1833. A lithographic stone is coated with a solution of asphaltum in oil of lavender and exposed to light under a half-tone negative, the film of which has been turned on the glass to secure the necessary reversed position, effecting a slow change in the asphaltum. The parts thus affected by the light become insoluble in turpentine, leaving the other parts soluble. Thus a (reversed) positive is rendered on stone, which, owing to the unctuous nature of its composition, can be prepared for printing purposes in the usual manner. The method most commonly used is the albumen process, invented by Poitevin in 1855. In this case the stone is coated with albumen in solution with bichromate of potassium, which is much more sensitive to light action than asphaltum. After exposure the stone is immediately covered with printing ink, to prevent further action, and washed with water, which removes the parts that remain soluble, while the ink adheres only to the parts that have become insoluble.

Transferring Process.—Unless limited editions are required, designs that have been drawn or engraved on stone are very rarely printed from directly. By means of the transferring process one design may be reproduced as many times as the relative size of the work and sheet to be printed will allow—ensuring greater economy in printing and greatly reducing the risk of damage to the original drawing stone. Transfer impressions are taken on a paper coated with a sizing of starch and glycerine, with a specially prepared ink. These impressions are laid in their proper position on a sheet of paper of the required size and fastened to it by means of pricking with the dull point of an engraving-needle. The sheet, the transfers adhering, is laid face down on a clean, polished stone or aluminum plate and repeatedly pulled through a hand-press, until the transfers adhere firmly to the stone, the paper being frequently dampened during this process. This done, the sheet is carefully raised from the stone, leaving the thin paper transfers still adhering to its surface. These then in turn are dampened and carefully removed. A weak solution of gum and water is applied and the stone rolled up repeatedly with printing ink.

LITHOTOMY—LITITZ

To make the transfer ready for printing, it is etched in the same manner as an original drawing. In chromo-lithography the first transfer made is always that of the key-plate, supplied with register marks. The impression from this transfer is mounted on a sheet of aluminum or zinc and coated with shellac to ensure against stretching or shrinking. All succeeding transfers are "stuck-up" or fixed on this key-sheet, in order to enable an accurate register of the colors.

Lithographic Printing.—The lithographic hand-press differs essentially from both the type and copper-plate hand-presses, a scraper being used instead of the vertical pressure of the platen. It consists of a frame provided with rollers on which the bed runs to and fro, the scraper or impression-bar and a tympan of leather, fitted to an iron frame hinged to that end of the bed nearest the scraper. The scraper consists of a flat piece of box-wood, beveled on both sides and covered with leather. The manner of printing is as follows: the stone with the design upon it is placed face up upon the movable bed, then moistened with a sponge, rolled up with ink and the sheet which is to take the impression, laid thereon. Several sheets of paper are placed over it to secure the necessary backing, the tympan lowered upon it to cover the entire bed and stone, and the carriage brought forward under the scraper. Pressure is applied by means of a hand-lever at the side of the press, and the entire length of the bed passed under the impression bar. The pressure is then released, the bed brought back to its original position, the tympan raised and the printed sheet taken off. Until the introduction of the lithographic power-press in 1867, this method of printing was exclusively used for lithographic printing. At the present time its only utility is for the purpose of making artist-proofs and transfers for printing on power-presses. The lithographic power-press differs but slightly from that of the typographic power-press. The principle of operation remains the same, taking in place of the letter-press form a lithographic stone in its bed and being supplied with a contrivance for distributing the moisture with which the stone must be covered before the ink is applied. The use of rotary printing-presses, with an increased speed of 50 per cent over the flat-bed presses, has been made possible by the substitution of the flexible aluminum plate for lithographic stone, and has opened the field of multi-color printing by the lithographic process, whereby two or more colors are printed in rapid succession before the sheet is delivered. The rotary press consists principally of two cylinders—one to hold the plate and the other to furnish the pressure—and is supplied with a mechanism similar to that of the flat-bed press for distribution of moisture and ink. Rotary presses having two and three plate cylinders and printing respectively two and three colors each time a sheet is fed are already largely in use, and four-color presses are now being built on the same general principle.

OTTO W. WILHELM, Of Sackett & Wilhelms Lithographing and Printing Company, New York.

Lithotomy, in surgery, the operation of cutting for the stone. (See CALCULUS.) As usually performed it consists in cutting by the side of the anus in the perineum, so as to reach and divide the urethra and neck of the bladder, where it is surrounded by the prostate gland. A grooved and curved staff is introduced into the bladder first, and then the incision is made in the perineum to reach the bladder, the groove in the staff serving as a guide to the knife. When the calculus or stone is felt with the finger the staff is withdrawn and the stone extracted by means of forceps, proper treatment to ward off inflammation and other accidents being then adopted. When thus performed, unless there be unusual difficulties, the length of time required to extract the stone is seldom more than three minutes, often one or one and a half. At first the urine escapes through the wound, but in favorable cases it issues by the natural passage within a week, and the wound heals in the course of a month.

Lith'otry, in surgery, the operation of crushing a stone in the bladder into fragments of such a size that they may be expelled by the urethra. The instrument, called a lithotrite, by which the stone is broken up, is introduced in the same manner as a catheter or sound into the bladder, and after catching the stone crushes it to pieces. The instrument has two movable blades at the extremity introduced into the bladder, and these are brought together to crush the stone by means of a powerful screw. This operation is only applicable where the bladder is not irritable, where the canal of the urethra is of good size, and the stone small. It is inapplicable to children, but this is the less to be regretted, because there is perhaps no surgical operation more generally successful than that of lithotomy in children. In lithotry care must be taken that no portions of the stone are left in the bladder, as such fragments are almost certain to form the nuclei of fresh concretions.

Lithuania, lith'-ū'-ā-ni-a, Russia, a historic grand-duchy of 60,000 square miles, united in 1569 to Poland, and since the dismemberment of that kingdom in 1773, 1793, and 1795, forming the Russian governments of Mohilev, Vitebsk, Minsk, Vilna, and Grodno, and portions of the Prussian province of Gumbinnen and East Prussia. The Lithuanians, who are of Lettish origin (see LIVONIA), were in the 11th century tributary to Russia, but they made themselves independent when Russia was divided by the troubles under the successors of Vladimir. Ringold, in 1235, bore the title of grand-duke, and under his successors the whole of Russian Lithuania became independent. Vladislaus Jagello, by his marriage with the Polish queen Hedwig, united Lithuania and the conquered Russian provinces with Poland.

Lititz, lit'its, Pa., borough, in Lancaster County; on the Reading & Columbia railroad;

LITMUS — LITTLE FALLS

about 28 miles southeast of Harrisburg, and 8 miles north of Lancaster. The first permanent settlement was made in 1757 by Moravians. Some of the United Brethren had formerly lived in Bohemia and they named the place after their old home. They showed their loyalty to their new country by providing shelter, food, and care for wounded soldiers of the Revolutionary War. The graves of some of the early patriots are still pointed out. Lititz is situated in a region where there are many good farms, but its chief industries are in manufacturing. The principal manufactures are corn-starch, knit-goods, cocoa, chocolate, cigars, and some dairy products. The mineral springs are noted and much frequented. The borough is the seat of Linden Hall Seminary, established in 1794. Pop. (1900) 1,637. Consult: Mombert, 'History of Lancaster County, Pa.'; Moravian Historical Society Records.

Lit'mus, or *Lacmus*, is a blue pigment obtained from any lichen which yields archil. (See *LICHEN*, *Fungi*) The plant, bruised between stones, is exposed to the air for several weeks, and moistened with some liquid containing ammonia, lime and potashes being also added. Fermentation sets in, the lichen becomes red and finally blue, and when it has acquired the proper tint, chalk or sulphate of lime is added, and the soft paste is made into square cakes by pressure in molds, and the cakes are then dried. Litmus is complex in nature; it contains several coloring matters of definite composition, which can be separated by the use of glacial acetic acid and absolute alcohol.

Lit'olff, Henry Charles, European composer and pianist: b London 6 Feb. 1818; d. Paris 6 Aug. 1891. He studied pianoforte playing under Moscheles, and made his first public appearance as a pianist at the Covent Garden Theatre, London, in 1832. At 17 he went to France and for some time lived a wandering life traveling in France, Holland and Germany, giving concerts. In 1851 he settled in Brunswick, married the widow of the music-publisher Meyer, and took control of the business; later he transferred the management of affairs to his adopted son, who began the publishing of cheap editions of classical music. In 1860 he moved to Paris, and married the daughter of the Count de la Rochefoucauld. His compositions include piano pieces (including the 'Spinnlied'); symphony concertos; and the operas 'Héloïse et Abelard'; 'Die Braut von Kynast'; 'Les Templiers,' and 'King Lear.' As a pianist he showed feeling and brilliancy of execution, but was uneven, and sometimes inaccurate.

Litop'terna, a South American perissodactyl of the Tertiary Period, related to the ancestors of the horse. See *HORSE*, *Fossil*.

Litor'i'na. See *PERIWINKLE*.

Litre, *lē-tēr*, or *Liter*, the French standard measure of capacity in the decimal system. It is a cube, each side of which measures 3.937 inches, and it contains 61.028 cubic inches, or 2.113 pints. See also *METRIC SYSTEM*.

Littell, *lē-tēl'*, *Eliakim*, American publisher: b. Burlington, N. J., 2 Jan. 1797; d. Brookline, Mass., 17 May 1870. He learned the printer's trade, and in 1819 established at Philadelphia a literary periodical, the 'National Recorder,' the name of which was changed in 1821

to the 'Saturday Magazine.' In 1822 he began to publish a monthly, the 'Museum of Foreign Literature and Science,' giving selections from the best periodical literature of Europe. In 1844 he started in Boston 'Littell's Living Age,' a weekly literary eclectic periodical which is still continued.

Little, James Stanley, English writer on literature and art: b. Herne Hill, Surrey. He has lectured in England, on South Africa and imperial federation, edited 'African Review' 1895-7, and 1901-2, and has published 'A World Empire' (1879); ('South Africa') (1884); ('What is Art?') (1884); ('The United States of Britain') (1887); ('A Vision of Empire') (1889); ('The Progress of the British Empire in the Century') (19th Century Series) (1901); etc.

Little Blue Creek, a small stream in Jackson County in the western part of Missouri. A contest occurred, in 1864, on the banks of this stream, between Federal troops under General Curtis and Confederate troops under General Sterling Price. The contest lasted several hours, when the Confederates fell back on Big Blue Creek, in the same county, and made a strong resistance. The Union cavalry, under General Pleasanton, finally routed the Confederates, who retreated into Arkansas.

Little Colorado, a river which has its rise in the western part of New Mexico, and flows southwest into Arizona, where the course changes northwest to its junction with the Colorado River. The amount of water is sometimes large, but again the river resembles a chain of small lakes or ponds, with dry or nearly dry river beds in many places. The river is about 230 miles long. It flows a little south of the southern boundary of the Navajo Indian Reservation, around the region where many "Cliff Dwellers" once lived in Arizona, and on through arid wastes and among low mountains to near the Colorado, where it enters a deep cañon, through which its waters flow into the Colorado just at Marble Cañon.

Little Corporal, The, a name bestowed upon Napoleon by his admiring soldiery after the battle of Lodi, in affectionate allusion to his small stature.

Little Dorrit, a novel by Charles Dickens (q.v.) published in 1856. There is but a slight plot to the story, which contains more than 50 characters.

Little E'gret, any of several small, white herons. See *EGRET*; *HERON*.

Little Falls, Minn., city and county-seat of Morrison County; on the Mississippi River, and on the Northern Pacific railroad; about 100 miles northwest of St. Paul. The place was settled in 1856, and in 1889 was incorporated. A dam across the river aids in furnishing extensive water-power. It is situated in an agricultural and lumbering region. Its chief manufactures are flour, lumber, machine-shop products, paper, bricks, beer, and dairy products. It is the commercial centre for a large part of Morrison and adjoining counties. It has a fine court-house, Saint Gabriel's Hospital, Saint Otto's Orphan Asylum, a city library, and several good school buildings. Pop. (1890) 2,354; (1900) 5,774.

Little Falls, N. Y., city, in Herkimer County; on the Mohawk River and the Erie

LITTLE GIANT—LITTLE ROCK

Canal, and on the West Shore and the New York Central & H. R. R.R.'s; just midway between Albany and Syracuse. Where the city is now was once the site of an Indian village, and was visited in the 17th century by missionaries. A white settlement was made here about 1770 or a few years later. In 1782 this settlement was destroyed by Indians and Tories, and no successful efforts were made to rebuild until 1790, when a colony of Germans took possession. The place was incorporated as a village in 1811; the incorporation was changed in 1827. It became a city in 1895. The city gets its name from the falls, or series of cascades in the river, which descends 45 feet in less than a mile. General Herkimer, a Revolutionary officer, is buried in a cemetery near the city.

Little Falls is situated in a grazing region noted for its dairy products; but the city is noted for its manufactures. The country around is rolling and is diversified by many low hills, but along the Mohawk, where Little Falls stands and in the vicinity, there are peculiar rock formations. The chief manufactures are knit-goods, paper, carriages, bicycles, leather, knitting machinery, foundry and creamery products, and book-cases. There are about 2,500 employees in the manufacturing establishments. The two banks have a combined capital of \$350,000; the annual amount of business is about \$2,750,000. The city has a number of fine church buildings, a city hospital, a public school library, an excellent high school, public and parish schools, and a number of fine public and private buildings. Pop. (1890) 8,783; (1900) 10,381.

Little Giant, The, a familiar name applied to Stephen A. Douglas (q.v.) by his political admirers in allusion to his small stature and great intellectual capacity.

Little John, one of the outlaw comrades of Robin Hood. He was famed for his strength and was the only one of the company who could approach Robin Hood in skilful handling of the bow. By some authorities his name is supposed to have been John Nailor.

Little Kanawha, kā-nā'wā, a river which has its rise in the central part of West Virginia, flows west and northwest, and enters the Ohio River at Parkersburg. It is about 100 miles long, has considerable rapidity in the mountain section, and is of benefit as a route for the transportation of the oil and lumber of that portion of the States through which the river flows. It has been made navigable as far as Burning Springs, about 40 miles from Parkersburg.

Little Lord Fauntleroy, a popular story for children by Mrs. Frances Hodgson Burnett, originally published in 1885 as a serial in the magazine "Saint Nicholas."

Little Mac, a nickname applied by the soldiers of the Union army during the Civil War to General George B. McClellan (q.v.).

Little Nell, a child character in the novel "Old Curiosity Shop," by Charles Dickens. She was reared amid vice and crime, yet preserved a beautiful purity of character.

Little Phil, a nickname given by his soldiers to General Philip H. Sheridan (q.v.) during the Civil War.

Little Red Riding Hood, a well-known fairy tale which first appeared in Paris in 1697, in a collection of tales by Charles Perrault.

Little Rock, Ark., capital of the State, the seat of Pulaski County, and the largest city in the State; on the St. Louis, I. M. & S., the Rock Island, and the St. Louis S. railway systems; 133 miles west of Memphis, 346 miles southwest of St. Louis, 165 miles west of Fort Smith, and 145 miles northwest of Texarkana. Little Rock is situated on both banks of the Arkansas River, and takes its name from the rocky promontory which rises on the south bank some 50 feet above the river, now used as one of the abutments of one of the four bridges which span the river. This rock is the first seen in ascending the river, and was called the Little Rock, in contradistinction to the bold precipice, about ten times higher, which rises some three miles above upon the opposite bank, and called the Big Rock. This commanding eminence is now the site of an army post. While the eastern border of the city touches rich alluvial cotton lands, without rocks and subject to a high state of cultivation, its western border reaches to the foot-hills of the Ozark Mountains. It is situated near lat. 35° and lon. 92°, almost at the centre of the State. The Arkansas River is navigable up to this point during the major portion of the year for large steamboats, while smaller vessels may as far up as Fort Smith.

Trade and Commerce.—The growth of the commerce of Little Rock has been gradual but steady. The total business for 1902 is estimated at \$50,000,000, a large portion of which consisted of cotton and its by-products. During the season of 1901-2 Little Rock shipped 246,675 bales of cotton. The total freight traffic for 1902 employed 83,405 cars. The real estate transactions during the same year aggregated \$2,495,882. The postal receipts for the fiscal year ending 30 June 1903, totaled \$116,036. The Board of Trade, the Retail Grocers' Association, and the Merchants' Freight Bureau are organs for concert of action among business men.

Manufactures.—The largest single industry is the manufacture of cottonseed-oil. There are four mills, which shipped during the season of 1901-2, 727 cars of oil, 1858 cars of meal, and 473 cars of hulls. Of other industries, besides domestic and jobbing shops such as clothing, food, plumbing, etc., the principal are foundries, railway shops, a cotton mill, ice and printing plants, 4 compress companies, beer and bottling works, and wagon shops. The census report shows that in 1900 the city contained 171 manufacturing establishments with \$3,434,393 capital, employing 2,751 persons, paying \$1,384,722 in wages, and \$1,900,081 for materials, and having a total output of \$4,723,118.

Banks.—On 1 Nov. 1903, there were three national banks and 12 State and savings banks, with a capital stock of \$1,875,000 and surplus of \$563,410, and deposits amounting to \$6,211,117. The local bank clearings for the year 1902 aggregated \$48,521,981.99. Besides these, there are 13 building and loan associations, all local, with aggregate stock amounting to \$8,335,010, and loans in force aggregating \$2,605,316.

Government and Finances.—All municipal corporations in Arkansas are governed by general laws, and not by special charter. The mayor, treasurer, police judge, city clerk, and

LITTLE ROCK

city attorney, as well as the aldermen, are elected biennially. The city council is composed of the mayor and 16 aldermen, two of whom are elected from each of the eight wards by the voters of the entire city, and are required to reside in their several wards. The administrative officers are partly appointed by the mayor and partly elected by the council. The ordinary expenses of the city for the year 1902, not including the schools, aggregated about \$180,000, of which \$37,225 were expended for the police department, and \$36,504 for the fire department. The net bonded indebtedness is \$78,000. There is a floating indebtedness of \$11,000, a judgment debt of \$21,000, and a disputed claim of some \$60,000. The assessed valuation of real and personal property in 1902, on a basis of about 40 per cent of the full value, was \$15,971,236. The rate of taxation was as follows: State 5 $\frac{3}{4}$ mills; county, 9 $\frac{1}{4}$ mills; city 6 mills; school district, 5 mills, making a total of 26 mills. Counties and cities and towns are prohibited from levying taxes in excess of five mills on the dollar, except that they may levy a tax not exceeding five mills on the dollar to pay indebtedness existing at the time of the ratification of the State constitution (1874), and that counties may levy a road mill tax not exceeding three mills. Besides the revenue derived from the tax on real and personal property, the city received in 1902 from police court fines the sum of \$43,734.05; from general licenses, \$39,654.40; from the vehicle license, \$11,238.00; from miscellaneous sources \$8,691.79.

Churches and Charitable Institutions.—Little Rock is a city of numerous churches. There were in 1902, 73 churches and chapels (of which 37 were colored) with a total membership of 13,600; the two strongest denominations being the Methodist and the Baptist. It is the seat of Roman Catholic and Protestant Episcopal cathedrals, Saint Andrew's and Trinity. The former, at the corner of Seventh and Louisiana streets, is a noble edifice built of native granite, the most striking piece of architecture in the city. Other notable buildings are Christ Church (P. E.), the Eighth Street Methodist, the German Evangelical Lutheran, the First Presbyterian Churches and the Jewish Temple. Of the charitable institutions the more notable are the county and city hospitals, Saint Vincent's Infirmary, conducted by the Sisters of Mercy, the Children's Home, the Methodist Orphanage, the Jane Kellogg Home for Aged Women, and the Home for Aged Colored Women.

Buildings, Parks and Suburbs.—Little Rock is noted for the beauty of its homes. The profusion of its flowers have won for the city the name of "the City of Roses." All of the State's public institutions except the University of Arkansas at Fayetteville and the Branch Normal Institute for colored youth at Pine Bluff are located here. These include the State House, the School for the Blind, the Deaf-Mute Institute, the Lunatic Asylum, and the State Penitentiary. The State is erecting a new Capitol, to be built of Arkansas marble. Other public buildings of note are the Pulaski County Court house, constructed of granite quarried in the vicinity, the Custom House and Post Office, and the Board of Trade building. Of club houses are the Country Club, the Athletic Association, the Quapaw Club and the Elks' Lodge, social organizations, Concordia Association, a Jewish

club, the Masonic Temple, and the Albert Pike Consistory. The City Park, consisting of 35 acres of ground, is situated in the heart of the residence portion of the city, and is tastefully laid out in walks and drives, and well kept up. The Arkansas River is crossed by three railroad bridges and a free bridge erected by Pulaski County at an expense of nearly \$400,000, uniting the northern and southern portions of the city. There are two incorporated suburbs of the city, namely, Baring Cross, a thriving town of 800 inhabitants lying north of the Arkansas River and west of the city limits, and North Little Rock, a small town lying north of the river and of the city. A new suburb on Pulaski Heights, a picturesque hill overlooking the city, has recently been brought into prominence by the extension of the street car system, and promises to become fashionable for residences. Mount Holly, the oldest cemetery in the city, is beautifully adorned with shrubs and flowers, and has many fine monuments. Other cemeteries are Oakland, the Jewish, the Catholic, the National, the Confederate, and the Colored. The city is abundantly supplied with pure water obtained from the Arkansas River. There are two reservoirs with a storage capacity of 11,000,000 gallons, with an average daily consumption of 3,250,000 gallons. There are 65 miles of water mains in the city.

The streets are laid out with regularity. The principal retail thoroughfares are Main and Markham, the former running north and south and at right angles to the latter. There are within the city 239.61 miles of opened streets, of which 3 $\frac{1}{2}$ are paved with brick, granite and asphalt, and 8 miles with Telford and macadam pavement; 47.6 are graveled, and 105 are graded. The city has entered upon a new era as to the improvement of its streets. In addition to a tax of 3 mills collected exclusively for the improvement of highways, the city collects for the same purpose a vehicle tax. The recent discovery of asphalt beds in Arkansas is expected to lead to great improvement in road making in the city. Perhaps no other city of the same size will enjoy better street railway facilities than Little Rock when the projected improvements are added. The street railway company is now operating 25 miles of line within the city limits. The extensions to Pulaski Heights and on the north side of the river, when completed, will add 6.5 miles.

Education.—The single school district of Little Rock is a corporation distinct from the city, its territory including only that portion of the city which is south of the river. In 1902 it had ten schools, with 14 buildings, of which four schools with five buildings were for the colored children, 93 teachers, and an enrollment of 5,140, of whom 1,670 were colored. The school census for the same year showed a total of 11,535 who were entitled to attend the schools, of which number 4,407 were colored. This school district is perhaps unique in possessing a commodious and well furnished school board building, with rooms for meetings of the board of directors, for the superintendent and secretary, and for the teachers' meetings. The North Little Rock school district, including so much of the city as lies north of the river, had in 1902 five school buildings, two of which were for colored children, 15 teachers, and an attendance of 885. The school census showed that

LITTLE ROCK—LITTLE TURTLE

2,600 were entitled to attend the public schools in that district. Besides the public schools, there are private and parochial schools. For higher education, the University of Arkansas, the main departments and buildings of which are located at Fayetteville, has branch schools of law and medicine located here. Besides these are the Arkansas Military Academy, a military training school for boys, Maddox Seminary for young ladies, and the Philander Smith College for colored youth.

History.—When the territory now known as Arkansas passed to the United States in 1803, the site of the future capital was an unbroken wilderness. By the act of Congress of 2 March 1819, the seat of government of the newly created territory was fixed at the Post of Arkansas on the Arkansas River some 30 miles above its confluence with the Mississippi. On 24 Oct. 1820, an act was passed removing the capital to Little Rock. It has been aptly said that so manifest was the destiny of the future city that it was made the seat of government before it had become a town. A post-office was established on 10 April 1820. It was incorporated as a town 27 Oct. 1825. It is said that the inhabitants numbered only 450 in 1830. On 2 Nov. 1835, it was, by special act, incorporated as a city. When the momentous question of secession arose in 1861, a convention was called by the legislature to meet at Little Rock to discuss the subject. It met on 4 March, and, after considering the matter, adjourned without definite action on 21 March, subject to recall. On 6 May 1861, when war was already flagrant, the convention, being recalled, with only one dissenting vote, adopted an ordinance dissolving the union existing between the State of Arkansas and those united with her under the compact entitled, "The Constitution of the United States of America." On 10 Sept. 1863, Little Rock was captured by the Northern army under Gen. Steele, and remained in possession of the Federal forces during the remainder of the war. The unexpected increase in the population between the years 1860 and 1870, covering the period of the Civil War, may perhaps be attributed to the fact that during that period of disintegration society was forming new associations. The growth of the city since 1880 has been constant and rapid.

Newspapers.—The city has three daily and several weekly newspapers. The Arkansas *Gazette* was originally founded by Wm. E. Woodruff, Sr., at the Post of Arkansas in 1819, and has been continuously published ever since under the same name, except when it was suspended for a short time during the war. When the seat of government was removed to Little Rock in 1820, it followed in the wake of the government, and issued its first number at the new capital on 29 Dec. 1821. Its subsequent growth has been closely linked with that of the city.

Population.—The population of Little Rock in 1850 was 2,167; (1860) 3,727; (1870) 12,380; (1880) 13,138; (1890) 25,874; (1900) 38,307, of whom 23,500 were white, and 14,717 were colored. Of these 38,307 inhabitants, 2,099 were foreign born, while 36,307 were native. In 1904, population was 55,000. T. D. CRAWFORD,

Supreme Court Reporter, Little Rock, Ark.

Little Rock, Capture of. The State authorities of Arkansas seized the United States

arsenal at Little Rock 8 Feb. 1861, and until 10 Sept. 1863 the city remained in Confederate occupation. After the fall of Vicksburg and Port Hudson, 4 and 8 July 1863, Gen. F. Steele was ordered from Vicksburg to Helena and directed to form a junction with Gen. Davidson, who was moving south from Pilot Knob, Mo., break up Sterling Price's army, and occupy Little Rock. Steele arrived at Helena 31 July and organized his expedition, finding at that place two divisions of infantry, a brigade of cavalry, and 39 guns; in all, about 7,000 men. On 5 August he marched for Devall's Bluff on White River, reached it without incident, and there was joined by Davidson with 6,000 cavalry and three batteries, making his force about 13,000 men and 57 guns. A few days later he was joined by a brigade which raised his aggregate to over 14,000, of whom 10,500 were effective, many being sick. August 24 Davidson's cavalry advance skirmished with Marmaduke's cavalry up to and through Brownsville and up to his intrenchments at Bayou Meto. Davidson fell back to Brownsville, where, 2 September, Steele joined him, and concentrated all his available force. The position on the Bayou Meto, 12 miles from Little Rock, was flanked, and on the 7th Steele reached the Arkansas River near Ashley's Mills, where Davidson's cavalry had a sharp skirmish and drove the Confederates across the river. Steele repaired the main road back to Bayou Meto, and on the 10th Davidson crossed to the south side of the river by a pontoon bridge and marched on Little Rock, but ten miles distant, Steele marching along the north bank. The city was defended by Sterling Price with about 7,700 men, of whom 6,500 were intrenched on the north side of the Arkansas, and about 1,200 on the south side, on the line of the Bayou Fourche, about five miles from the city. Davidson moved directly on the city, without much opposition until he reached Bayou Fourche, where he found Marmaduke's cavalry, dismounted, a brigade of infantry, and two batteries, all drawn up to oppose him. Davidson attacked on two roads, driving the Confederates back; Steele, who had marched abreast of him on the opposite side of the river, opened an enfilading artillery fire; and Marmaduke fell back through the city, closely followed by Davidson's cavalry. Price had withdrawn from the north bank of the river when he learned that Davidson had turned the position, and evacuated the city at 5 P.M., retreating to Arkadelphia. Steele's cavalry followed Marmaduke's cavalry for a day, and returned to Little Rock on the 12th. At 7 P.M. the city was formally surrendered to Davidson by the civil authorities. Price burned eight steamers, one of them a powerful gunboat, but the arsenal was saved. Steele reported a loss of 137 killed, wounded, and missing; Price reported a total loss of 64. Consult: "Official Records," Vol. XXII.; Lossing, "History of the Civil War," Vol. II.; The Century Company's "Battles and Leaders of the Civil War," Vol. III.

E. A. CARMAN.

Little Turtle, an Indian chief of the Miami Nation, one of those who signed the Treaty of Greenville in 1795. He visited President Washington in Philadelphia in 1797. He

LITTLE WOMEN — LITTRROW

was celebrated for his courage, ability and shrewdness. With his native forces he defeated General Harrner on the Miami River in 1790, and General St. Clair in 1791.

Little Women, a popular story for children by Louisa M. Alcott (q.v.), published in 1868.

Lit'tlefield, Walter, American journalist: b. Boston 17 March 1867. He was educated at Harvard and has been since 1897 on the editorial staff of the *New York Times*. He is the American correspondent of *Le Siècle*, Paris, and the author of 'The Truth about Dreyfus.' He has edited 'The Letters of an Innocent Man (Dreyfus)' (1898), and other works.

Lit'tleholes, George Washington, American hydrographic engineer: b. Schuylkill County, Pa., 14 Oct. 1860. He was graduated from the United States Naval Academy in 1883. He is an associate editor of the 'International Journal of Terrestrial Magnetism,' and has published, 'The Development of Great Circle Sailing'; 'The Methods and Results of the Survey of Lower California'; 'The Magnetic Dip or Inclination'; 'The Azimuths of Celestial Bodies'; and other works, all published by the United States Navy Department.

Lit'tlejohn, Abram Newkirk, American Protestant Episcopal bishop: b. Florida, Montgomery County, N. Y., 13 Dec. 1824; d. Williamstown, Mass., 3 Aug. 1901. He was graduated at Union College in 1845 and took orders in the Episcopal Church in 1850. He was rector of St. Paul's, New Haven, Conn., 1851-60, and of Holy Trinity Church, Brooklyn, N. Y., 1860-9. He was made bishop of Long Island in 1869, and from 1874 was in charge of American Episcopal churches on the continent of Europe. He wrote 'Philosophy of Religion'; 'The Christian Ministry'; etc.

Littlejohn, John Martin, American physiologist and osteopathist: b. Glasgow, Scotland, 1867. He was graduated from the University of Glasgow, afterward studied theology and was ordained in 1886. He was a tutor in Glasgow University, principal of Rosemont College 1890, of Amity College, Iowa, 1894-7, and has been president of the American School of Osteopathy, Kirksville, Mo., from 1900, and professor there from 1897. He has published 'The Political Theory of the Schoolmen and Grotius' (1894); 'Text Book on Physiology' (1898); 'Lectures on Psycho-Pathology' (1900).

Lit'tleton, or Lyttleton, Sir Thomas, English jurist: b. Frankley, Worcestershire, 1402; d. there 23 Aug. 1481. He was a student at the Inner Temple, sheriff in 1447, recorder of Coventry in 1450, and in 1453 was made sergeant-at-law. After holding several other legal appointments he became justice of the common pleas in 1466. He was created a knight of the Bath in 1475. His treatise on 'Tenures,' with the well-known commentary by Sir Edward Coke, was long the standard authority on the English law of real property. It was written in legal French, and first published at London about 1480. There are many subsequent editions.

Littleton, N. H., town, in Grafton County, on the Ammonoosuc River, and on the Boston & Maine railroad. When it was first settled in 1770, it was called Apthrop. When it was in-

corporated, in 1784, the name was changed to Littleton. It is in a section of the State noted for its beautiful scenery and cool summer climate. The river furnishes considerable water-power; and the town has several manufactures. Its chief manufactures are shoes, gloves, wagons and carriages, whetstones, bobbins, stereoscopic views, wooden ware, and furniture. It has a good public library; the building is a gift from Andrew Carnegie. The government of the town is administered by means of the annual town meeting. Pop. (1900) 4,066.

Littoral Deposits. See SANDSTONE.

Littré, Maximilien Paul Emile, mäk-sil-mil-i-öñ pôl ä-mé'l le-trä, French philosopher: b. Paris 1 Feb. 1801; d. there 2 June 1881. After completing his course at school his study of medicine was interrupted by the death of his father. He then engaged in teaching for a livelihood, took an active part in the revolution of 1830, and soon after was invited by Armand Carrel, editor of the 'National,' to write for that paper. In 1839 he published the first volume of an edition of Hippocrates in the original, with a French translation and copious notes. This work, in 10 volumes, secured his admission to the Académie des Inscriptions et Belles-Lettres. He translated Strauss's 'Leben Jesu,' and having adopted Comtist principles, wrote an able and lucid synopsis of them in his 'De la Philosophie Positive' (1845). In 1854 he was appointed editor of the 'Journal des Savants' and in 1863 commenced the publication of his great work, the 'Dictionnaire de la Langue française,' which has been called the best dictionary of any living language yet published. This was finished in 1873, two years previous to which Littré had been admitted into the Académie Française. Another important work of his was an edition of Pliny's 'Natural History' with a translation and notes. During the siege of Paris he retired with his family to Bordeaux, and was appointed professor of history and geography in the polytechnic school there. He was afterward summoned to Versailles to take his seat in the senate, having been chosen by the department of the Seine. He became a life senator in 1874. Among Littré's other works are 'Application de la Philosophie Positive au Gouvernement des Sociétés' (1849); 'Conservation, Révolution et Positivisme' (1852); 'Paroles de Philosophie Positive' (1859); 'Histoire de la Langue française' (1862); 'Auguste Comte et la Philosophie Positive' (1863); 'Etudes sur les Barbares et le Moyen Age' (1867); 'Médecine et Médecins' (1871); and 'Littérature et Histoire' (1875).

Lit'trow, Joseph Johann von, Austrian astronomer: b. Bischof-Teinitz, Bohemia, 13 March 1781; d. Vienna 30 Nov. 1840. In 1807 he obtained the chair of astronomy in the University of Cracow, and in 1810 accepted a similar chair in Kasan, where he founded the observatory. He became in 1816 joint director of the observatory of Buda, and from this he removed in 1819 to become director of the observatory of Vienna. He completely reorganized this establishment, and in his lectures yearly attracted a numerous audience, not only of ordinary students, but of unprofessional persons, many of them strangers from abroad. His writings, chiefly on mathematical and astronomical subjects, are numerous, and have generally had

a very extensive circulation. By far the most popular of all is his 'Die Wunder des Himmels,' of which the 8th edition was published (1895-7). It ranks as one of the best works of astronomy for the use of general readers.

Littrow, Karl von, Austrian astronomer: b. Kasan, Russia, 18 July 1811; d. Venice 16 Nov. 1877. He was a son of Johann Littrow (q.v.) whom he assisted in the Vienna observatory from 1831, and succeeding him as director in 1842. He edited the works of his father, adding considerably to 'Die Wunder des Himmels,' and was the author of 'Populäre Geometrie' (1839); 'Verzeichnis der geographischen Ortsbestimmungen' (1844-6).

Liturgy (Greek *λειτουργία* means a public service; used at Athens to mean a public service which the richer citizens discharged at their own expense.) The Septuagint translators used the Greek word *leitourgos* for that service of God in the Sanctuary. In the Hebrew it had various kindred meanings; in the Old Testament it usually denotes the service of a Jewish priest, but in the New Testament it is used of any service rendered to God. In the 4th century, the word as applied to priestly ministrations was generally recognized; and while it continued in use as meaning any solemn service, it was applied especially to the Eucharistic service. It is in this sense that the word is used by the Greek Church when they say "Divine liturgy."

The records extant which show the exact liturgy of the Christian Church in the 1st century are more the allusions found in documents of the 2d century. From the year 150 there are numerous proofs to show the existence of a fixed order and fixed words for the service of the mass or for the Eucharistic service. This service or liturgy was not made just when mentioned by Cyprian, and in 138 by Justin, and many others who committed to writing the order of the services or the liturgy. But there is not sufficient proof to warrant the assertion that there was any entire written liturgy before the 4th century. As the liturgies exist to-day they may be divided into five groups or families of liturgies, distinguished from each other chiefly, though not entirely, by the different arrangement of their parts. Three of the groups are Oriental and two are Western. They are: (1) The West Syrian Group, which includes the Liturgies of Saint James, Saint Basil, Saint Chrysostom, and that of Armenia. In this group the intercession for the living and the dead is placed after the invocation of the Holy Spirit, which in Oriental liturgies follows the consecration.

(2) The Alexandrian Group, which includes three Greek liturgies; Saint Mark, Saint Basil, and Saint Gregory, also the Coptic liturgies. This group is characterized by the "Great Intercession" for the living and the dead being placed in the midst of the Preface.

(3) The East Syrian Group, includes the liturgies in the Syriac language as used by those who belong to the Roman Catholic Church. In this group the "general intercession" is placed between the words of institution and the invocation of the Holy Spirit.

(4) The Liturgies of Gaul and Spain. In this group the "Great Intercession" comes just after the offertory, though the Mozarabic liturgy

has a memento of the living before the Pater Noster.

(5) Gallican Liturgy. In this the intercession is divided, that of the living is before consecration, and that of the dead after consecration.

That part of the "Liturgy of the Mass" called the "Canon" is very ancient, and existed about as at present since the time of the Apostles (see MASS; MISSAL). The liturgy of the Church of England is derived from the Ephesine original through the ancient Gallican liturgy which was brought to France by Greek missionaries, who were accustomed to use the form known as the liturgy of Saint John. There is no invocation of the Holy Spirit in the present English form, although the Protestant Episcopal Church has restored the invocation, like the Scottish Episcopal Church. There is, however, no ritual element wanting in these two English forms whether they be compared with the Greek or Latin liturgies. The liturgy in use in the Protestant Episcopal Church more nearly resembles the Gallican liturgy than any other group, but in some respects there is a difference in arrangement, and also in meaning. There is no intercession for the dead, and the intercession for the living comes before the Communion.

There is a growing tendency among many of the Protestant Churches and denominations to adopt liturgical services.

Bibliography: Tertullian, 'De Corona'; Cyprian, 'Epistle'; Report of Council in Trullo; Probst, 'Liturgie der drei ersten Jahrhunderte,' who claims that there was a written liturgy before 150; Hammond, 'Ancient Liturgies'; Smith and Cheatum, 'Liturgies.'

Lituus, (1) a crooked staff, represented in works of art as borne by the ancient Roman augurs in their divinations. It was like a crozier in shape. (2) A trumpet, having a mouth which curved upward, and which was used by the Roman priests and cavalry. (3) In geometry, a spiral, of which the characteristic property is that the square of any two radii vectores are reciprocally proportional to the angles which they respectively make with a certain line given in position, and which is an asymptote to the spiral.

Liu-kuo, lē-oo'kē-oo', or **Loo-choo Islands**, Japan, a chain of 37 islands, mostly small, forming an integral part of the empire, and extending irregularly in a southwestern direction between Kiu-shiu and Formosa. The islands were conquered by the Prince of Satsuma in 1609. They constitute the Japanese prefecture of Okinawa, with an area of 1,863 square miles; pop. 160,000. Oshima and Okinawa are the only islands of considerable size. Capital, Shiuri in Okinawa. See JAPAN.

Liu-Kun-Yi, Chinese statesman: b. Hunan about 1820; d. Nanking 6 Oct. 1902. He received a military education, and though not a scholar held high official positions. In 1861 he commanded one of the armies raised to oppose the Taiping rebels, and defeated them by a series of successful maneuvers. At the time of the Boxer outbreak he was viceroy of Nanking, the so-called "southern capital" of China, and in spite of the vigorous anti-foreign agitation in his own province and the hostile attitude of the Imperial Government at Peking, he refused to join the anti-foreign movement, and used his foreign-

LIUT PRANT—LIVER

drilled troops to suppress all Boxer demonstrations. In this he was supported by the Viceroy of Wuchang, and these two viceroys prevented the spread of the Boxer movement to the valley of the Yang-tse-Kiang, and were consequently influential in protecting Chinese interests in the subsequent peace negotiations.

Liut Prant, li-oot' pránt, a king of the Lombards (q.v.).

Livadia, liv-ä-dé'a, or **Lebadea**, Greece, a town on the Hercyna, 52 miles northwest of Athens. It is defended by a castle; and has manufactures of cotton goods, and a trade in small articles of raw produce. Pop. 6,500. Higher up the river, in a narrow gorge, is the site of the ancient Hieron, or cave of Trophonius, and the fountains of Lethe and Mnemosyne.

Live-for-ever, or **Garden Orpine**, a small cultivated stonecrop, *Sedum telephium*. See STONECROP.

Live Oak, a species of evergreen oak found growing in various parts of the United States, Central America, and Cuba. See OAK.

Live Stock, Derivation of. The domestic animals of the world have all been derived from wild stock, from which they differ in a greater or less degree, according as the need and variety of their services have called for changes in the course of their development from original types. In some cases the original stock has been completely lost, so that it can only be inferred or remembered by tradition. In others it is perfectly well known from what natural species the domestic races in question have descended, and this animal may still be found in a wild state.

The cattle of the world are the product mainly of three lines of descent. First, that which gave rise to the ordinary breeds known in Europe, America, and all those parts of the world that have been colonized by Europeans; second, the Indian humped cattle; and third, the varieties of the Asiatic buffalo. The last named are merely domesticated races of the existing wild buffalo of southern Asia, which are adapted to swampy lands and have been spread throughout that part of the world inhabited by Malays, and also carried to Egypt, the Senegal region and some other territories.

The common cattle of the United States have come down to us apparently along two lines of descent, which are continually mingled, especially in the interior parts of the country. The cattle of New England and the eastern half of the country generally, were brought primarily, and have since been supplemented by occasional importations, from Great Britain and the Netherlands. This stock owes its origin to the domestication following the Roman conquest of western Europe of two species of wild oxen which roamed the forests of the continent of Europe, and were found numerously there by Cesar and his army. One of these was a long-horned kind which seems also to have been indigenous to the British Isles. The other was apparently more southerly and easterly in its distribution.

Our horses are the highly varied product of the domestication of a species of horse which became entirely extinct anterior to any records. Its home, no doubt, was in the highlands of central Asia, and it was probably a small, shaggy, big-headed, dun-colored animal, more nearly

resembling the Asiatic wild ass or kiang than anything else now known to us. It is possible that a separate pony was native to the forests of Europe, and that its blood may have been joined with that of the Asiatic horse in the formation of our present race, but of this we cannot be sure.

Sheep also are of unknown origin. It is probable, however, that they represent a combination of several species natives of the mountains of central Asia, some or all of which may be living but unrecognizable. The ordinary goat we know to be descended from the wild goat of western Asia, with possible admixture in the case of the Angora goats of the markhor or some other Himalayan species.

Swine are the domesticated races in Europe of the wild boar, which is still extant; and in the Orient of one or more local species of wild swine that still exist there in their native state.

Poultry are more easily traced than most of the larger domesticated animals. All of our barn-yard hens and chickens, curiously diversified as they have become, are the descendants of the jungle-cock of India, still to be shot among the foot-hills of the Himalayas. Similarly the ancestry of the peafowl, guineafowl and turkeys, is found in species of birds which we still know in a wild condition. Ducks and geese are of more diverse origin, but may be traced in most cases to the wild ducks and geese still prevalent in many parts of Europe and America, or else to certain well-known species of the Orient.

Liver. The liver is the largest glandular organ of the body. In man it is situated on the right side of the abdominal cavity immediately beneath the diaphragm. Its weight in the adult is approximately from 3 to 4 pounds, and its size is roughly indicated by the following measurements: greatest diameter about 12 inches, anteroposterior diameter about 7 inches, thickness at different parts from 1 to 3 inches. The organ is divided into five lobes, of which the right and left are the principal ones; the former comprising the greatest part of the bulk of the entire organ. On the under surface may be seen a square lobe lying anteriorly between the right and left lobes, and known as the quadrate lobe. In a similar position between the right and left lobes at the posterior part of the organ is the Spigelian lobe, while a bridge-like lobe extending from the latter to the right lobe is known as the caudate lobe. The upper surface of the right and left lobes is convex and fits into the arch of the diaphragm. The lower surface of the organ is more or less concave and is divided by five fissures. Of these a longitudinal furrow extends from the anterior to the posterior border of the organ separating the right from the left lobe; a transverse fissure extends at right angles from this at a point somewhat nearer the posterior than the anterior surface; it divides the longitudinal fissure into an umbilical fissure in front (so-called on account of its lodging the umbilical vein in the foetus) and the fissure of the ductus venosus behind (on account of its lodging the ductus venosus in the foetus). Between the lobus Spigelii and the right lobe of the liver is the fissure of the inferior vena cava, lodging that vein, while at the anterior edge of the organ at the side of the quadrate lobe is a fissure which accommodates the gall-bladder. The transverse fissure is the most important, as it serves for the

LIVER

entrance into and emergence from the organ of the blood-vessels, nerves, and hepatic ducts.

The liver is held in place by five ligaments, four of which are simple folds of peritoneum, while the fifth, or ligamentum teres, is a round cord formed by the obliteration of the umbilical vein and extending from the anterior edge of the liver at the notch between the left and right lobes to the umbilicus and along the under surface of the liver to its posterior border. The peritoneal folds which serve the purpose of ligaments are a longitudinal one extending on the upper surface of the organ from the notch in front to the posterior border, a coronary ligament which is found along the posterior border, and a right and a left lateral ligament. These peritoneal reflexions serve to hold the organ in place, keeping it more or less firmly in apposition with the diaphragm.

The blood-vessels entering the liver are the hepatic artery and the portal vein; the former being a branch of the celiac axis, the latter being the large venous trunk which is formed by the union of the superior mesenteric and splenic veins. Both the hepatic artery and portal vein divide in the transverse fissure into two parts, a right and a left, which enter the substance of the right and left lobes respectively.

The hepatic veins are the efferent veins of the liver conveying the blood from this organ into the inferior vena cava. In addition to these vessels, the liver, like other organs, is supplied with large and numerous lymphatics. The nervous supply of the organ is derived from the left pneumogastric, the hepatic plexus of the sympathetics, and from the right phrenic nerve. The bile ducts and hepatic ducts will be described below.

The gall-bladder is a small pear-shaped sac lying on the under surface of the liver. At its narrow end it opens into a small duct (cystic duct) which passes back and down to join the hepatic duct forming the common bile duct, which terminates in the duodenum. The gall-bladder is the reserve sac in which bile is stored and by the contracting of which a uniform flow of this liquid is maintained.

Structure of the Hepatic Substance.—The substance of the liver is made up of lobules of more or less equal size, separated by areolar connective tissue, which is a continuation of the fibrous covering of the organ or *capsule of Glisson*. In these fibrous septa between the lobules are found the larger blood-vessels, biliary ducts, lymphatics, and nerves. The lobule under a low power of the microscope is seen to be composed of radiating columns of liver cells converging to a central point in which is situated a large vein (intra-lobular vein) belonging to the system of the inferior vena cava. The columns of liver cells branch and anastomose with each other, and between them are spaces occupied by blood capillaries and the primary biliary passages. The liver cells themselves are polyhedral in shape, and are so arranged that a capillary space, known as the biliary capillary, is left between them. The capillary blood-vessels are similarly formed by the peculiar juxtaposition of the liver cells, leaving spaces in which the capillary blood-vessels extend from the terminal branches of the portal vein in the septa at the periphery of the lobules to the central vein already mentioned. The latter, collecting the blood from the capillary system, transports it to larger vessels known

as sublobular veins, which finally unite and form the hepatic veins and discharge the blood into the inferior vena cava. The hepatic arteries and their terminal branches occupy the septa and supply blood to the connective tissue constituting the septa, and to the walls of the portal veins and biliary ducts. The venous blood of this distribution is discharged into the terminals of the portal vein within the septa.

At the periphery of the hepatic lobules, the epithelial cells of the hepatic columns continue directly into the smaller bile ducts which are situated in the interlobular septa. These primary bile ducts unite to form larger ducts and finally a right and left hepatic duct emerging from the transverse fissure unite to form a common bile duct. This is further joined by the *cystic duct* or duct of the gall-bladder, and it terminates in the duodenum in a common orifice with the pancreatic duct.

The structure of the liver is such that the blood entering through the portal circulation comes in contact with the liver cells on one side while the capillary biliary passages are on the other side of the hepatic cell.

The lymphatic vessels accompany the portal vein and hepatic artery, and another system accompanies the branches of the hepatic vein. The capillaries penetrate into the lobules, passing between the hepatic cells.

Functions of the Liver.—The physiological functions of the liver are probably very numerous and are but imperfectly understood. The position of the organ indicates that one of its important functions is the elaboration of materials presented by the blood coming from the gastro-intestinal tract, and probably also the purification of this blood. As far as they are known, the functions of the organ may be divided into the *metabolic* and *biliary*.

Metabolic Functions.—It is known that the liver acts upon sugars and other carbohydrate materials to convert them into glycogen which is stored up by the hepatic cells. This accumulates during digestion and is utilized in the intervals, so that the percentage of sugar in the blood is kept at an approximately uniform standard. It is known that in certain diseases (for example, diabetes), this function is greatly disturbed with resulting consequences that affect the general health. The liver shares with the muscles of the body this glycogenic function.

Another important metabolic function is that of forming urea, the final stage in the metabolism of albuminous food. Uric acid also is to some extent formed in the liver but is more particularly the product of the lymphatic organs and tissues.

Biliary Function.—The formation of bile is one of the important attributes of the liver, though possibly this function is less predominating than has hitherto been believed. The bile is an albuminous liquid containing bile pigments (bilirubin, biliverdin), bile salts (glycocholate and taurocholate of soda), nucleo-albumin, cholesterol, fat, and other less important substances including various salts. The bile is secreted more or less intermittently, the amount being greatest about the middle part of the day and increasing after meals. The daily output is from one to two pints. Its functions are numerous. Among other properties it aids in the absorption of fatty foods, stimulates intestinal peristalsis, and prevents intestinal fermentation.

LIVER

and is the vehicle of excretion from the body of certain waste products, notably hemoglobin. It is known that bacteria and other minute foreign bodies are discharged from the system through this medium.

DISEASES OF THE LIVER.—The diseases of the liver may be classified under the following heads: Derangements of the Circulation; Nutritional and Inflammatory Disease of the Substance of the Liver; Tumors; Parasitic Diseases; Functional Disturbance.

Circulatory Disturbances.—*Congestion of the Liver* is an increase in the volume of blood in the organ. This may be transient or more or less permanent.

(a) Transient congestion follows the ingestion of food and drink, especially when these are of stimulating quality. It is also occasioned by circulatory activity, such as accompanies fevers and other conditions of systemic excitement. In these cases the increase of blood in the liver is the result of an excessive supply of blood to the organ.

(b) Passive congestion is the form in which the outflow of blood from the liver is interfered with. This form is likely to be more or less durable or permanent. Among the causes, the most important are diseases of the heart and the lungs, or any other cause of obstruction to the circulation in the thorax.

Pathological Anatomy.—In active or acute congestion no marked alteration is observed on examination of the organ. In passive congestion the liver becomes enlarged, and the central veins within the lobules are seen to be increased in size, while the peripheral parts of the lobule often become light-colored from degeneration of the liver cells. This gives the surface of section of the organ a peculiar appearance that has been well designated "nutmeg liver." When passive congestion is long continued, the hepatic cells, compressed by the dilated blood-vessels and otherwise disturbed in their nutrition, undergo atrophy, while at the same time some fibrous tissue growth replaces the degenerated hepatic cells, and the whole organ becomes darker in color from deposit of pigment from the stagnated blood. The result is that the organ decreases in size, becomes harder, and of a darker color than normal. The term *cyanotic or red atrophy* is given to this condition.

The symptoms of congestion of the liver vary with the kind, the degree, and stage of the disease. In acute congestion, such as follows over-indulgence in stimulating food and drink, a sense of heaviness in the region of the liver, and perhaps slight disturbances of digestion with general malaise constitute the symptomatology. In chronic or passive congestion, such as accompanies heart disease, the symptoms are quite distinctive. The organ increases in size so much that it is easily felt in the upper part of the abdominal cavity and it becomes tender or even acutely painful. Digestive disturbances are very common, partly as the result of the condition of the liver itself and partly as the result of the underlying condition which occasioned the congestion of the liver. Among these digestive symptoms, loss of appetite, difficult and painful digestion, nausea and vomiting are the most conspicuous. When the congestion of the liver is pronounced, more or less jaundice occurs.

This results from the thickening of the walls of the biliary ducts and the compression of the finer biliary channels by the swollen state of the organ. In marked cases, the jaundice may be intense; usually it is slight.

In the last stages of congestion of the liver when the organ has undergone cyanotic induration, the symptoms may be similar to those of cirrhosis (q.v.).

Treatment.—The treatment of congestion of the liver is directed primarily toward the relief of the condition which causes the congestion. In heart diseases, cardiac tonics are important. Sometimes a prompt relief is obtained by venesection. Depletion from the portal circulation by brisk purgation may also be efficacious, and regulation of diet is important as the congested organ is less able to withstand injurious effects of stimulating foods or drink than the healthy liver.

Diseases of the Substance of the Liver.—Among these may be considered: (1) Simple atrophy; (2) acute yellow atrophy; (3) fatty liver; (4) cirrhosis, and (5) abscess.

Simple Atrophy of the Liver occurs in cases of starvation or inanition from long continued disease. A frequent form is that called *pressure atrophy* which is found in cases of deformities of the chest, in which the ribs are pressed inward against the liver, and as a result of tight lacing. The substance of the organ does not change very greatly in atrophy, though the individual liver cells are smaller than normal and usually somewhat pigmented, giving the structure a darker color. The shape of the liver is often peculiar. In the case of deformities of the chest, the pressure exerted by the ribs may cause deep grooves in the surface of the liver, or there may be a single transverse furrow at the lower margin of the ribs where this is pressed against the organ. In the case of deformity from lacing, part of the right lobe is frequently elongated and extends directly downward from the body of the organ as a more or less attenuated process.

The function of the liver is probably not seriously impaired in any of these cases, though some disturbance undoubtedly occurs.

Acute Yellow Atrophy is a disease in which a marked fatty degeneration of the cells of the liver is the important change. It is a rather rare condition, occurring in youth and early adult life; and has frequently been found in persons of dissipated habits. Parturition is one of the determining causes, and probably in many cases the disease is due to the action of micro-organisms, or to some form of poisoning. Phosphorous poisoning may cause changes in the liver and general symptoms sometimes quite indistinguishable from those seen in acute yellow atrophy unassociated with such poisoning.

The liver is decreased in size, often to a remarkable degree. It is soft and on transverse section the substance is of a light yellow color with mottled areas of reddish or purplish hue, the latter being portions in which the substance is congested or in which hemorrhages have taken place.

Changes are found also in various other tissues of the body, showing that acute yellow atrophy is not wholly a disease of the liver but a general infection or intoxication, having its most marked manifestations in the liver.

LIVER

Symptoms.—After a period of indefinite digestive disturbances, acute jaundice, and marked nervous symptoms set in. The patient becomes deeply jaundiced, delirious, and sometimes comatose. In the course of ten days or two weeks the disease terminates fatally in a large percentage of cases. A small proportion of the cases recover. The treatment consists in stimulation or other measures called for by the general condition.

Fatty Liver.—There are two varieties of fatty disease of the liver, that known as *infiltration* and that termed *fatty degeneration*. In the former there is a deposition of fat in the liver cells, similar to that which is found in the subcutaneous tissues in ordinary obesity. In the latter the liver cells undergo destruction with formation of fat. Fatty infiltration may be the result of excessive supply of nutriment as in ordinary obesity, and is also found in certain states of general weakness and wasting, particularly in association with diseases of the lungs. In the latter cases, the cause is to be found in the deficient consumption of fat, owing to diminished oxygenation. Fatty degeneration may be caused by various infectious diseases, but is more particularly the result of poisoning with phosphorus, arsenic, mercury, and other poisons.

In fatty infiltration, the liver is enlarged, lighter than the normal organ in specific gravity and in color, and on section with a knife the increased fat is indicated by an oily character of the cut surface. In fatty degeneration the liver is usually diminished in size and the substance is of a friable softened character.

There are no characteristic symptoms of fatty infiltration, but the increased size of the organ may cause a local feeling of fulness and pressure, and vague disturbances of the general health may also be attributable to the condition. In fatty degeneration, the symptoms are equally obscure. That due to phosphorous poisoning may present itself with the symptoms of acute yellow atrophy (*vide supra*).

Cirrhosis of the Liver is the most frequent and important of the diseases of this organ. It is essentially a replacement of normal liver tissue by connective tissue, causing more or less hardening.

The causes of cirrhosis of the liver are numerous, though one in particular occupies a very prominent position on account of its frequency. The cause referred to is over-indulgence in alcohol, especially raw spirits, whence the terms alcoholic liver, gin drinker's liver, etc. It must not be supposed, however, that alcohol is the invariable cause. Over-eating, gouty conditions, syphilis, and various other infectious diseases may be followed by cirrhosis entirely like that caused by alcohol. It has been noted in the description of congestion of the liver that a form of cirrhosis (cyanotic induration) results from long standing congestion. Sometimes cirrhosis of a peculiar type is caused by obstruction of the biliary ducts. This produces a stagnation of the bile and an irritation of the substance of the liver that terminates in the formation of connective tissue.

Pathological Anatomy.—Two forms of cirrhosis of the liver are recognized. One, known as the *atrophic*, in which the liver is decreased in size; the other, *hypertrophic*, in which the organ is increased in size. In atrophic cirrhosis (hob-

nail liver, granular liver), the organ has an irregular nodulated or granulated surface, the irregularities being caused by the contractions of the connective tissue which forms the basis of this pathological state of the organ. The liver is decreased in size, though not always very notably. It is very firm, and on section the increased connective tissue can be recognized in the form of more or less distinct septa interlacing the lobules or groups of lobules of the liver substance. The lobules and groups of lobules are compressed by the contracting connective tissue, and as a result undergo atrophy and degenerative change. The connective tissue formation which is characteristic of this form of cirrhosis is found in the interlobular tissues surrounding the terminal branches of the portal vein. Consequently the portal circulation is obstructed, and congestion of the various abdominal organs whose blood is discharged through this circulation results. When cirrhosis has proceeded for some time, new channels of circulation may be established, by which the congestion of the abdominal organs is relieved. There results from this visible enlargement of the veins of the abdominal walls and increased size of the veins in the lower end of the oesophagus and in the rectum.

Hypertrophic cirrhosis of the liver is a form in which the liver is increased in size. The surface is usually smooth and the substance of a uniform character. This is due to the fact that the new connective tissue is uniformly distributed within as well as between the liver lobules. This form of disease may be the result of the same causes as the atrophic variety, but is more commonly due to obstructions of the flow of bile. Very commonly interference with the discharge of bile is found in this form, as interference with the circulation of blood is characteristic of the other variety.

Symptoms.—The symptoms of cirrhosis of the liver in earlier stages are very obscure and uncertain. Later interference with the portal circulation causes congestion of the mucous membrane of the stomach and intestines, with resulting disturbances of digestion, such as dyspepsia, vomiting, constipation, and even hemorrhages from the stomach or bowel. The spleen is enlarged from congestion of its substance and the last phase of the disease is marked by dropical effusion in the abdominal cavity (ascites). Cirrhosis of the liver is a chronic disorder which may extend over a period of many years and which may be arrested even after it has reached an advanced stage. Among the symptoms of hypertrophic cirrhosis are tenderness and increase in the size of the liver, the development of jaundice, and sometimes the occurrence of fever. The disease is more rapid in its course than the atrophic variety.

Treatment.—The treatment of this condition is preventative rather than curative. When due to alcohol it may be arrested if not too well advanced, by a control of the habit of drinking; and a restitution of normal conditions may be favored by careful diet, including mainly the avoidance of stimulating or irritating food, and of general excesses of diet. The use of saline waters may be beneficial. When advanced to the stage of dropsy of the abdominal cavity, depletive measures, such as are used for the relief of dropsies in general, may be useful; or it may be necessary to remove the liquid by tapping.

LIVER

Abscess of the Liver may result from dysentery and other ulcerative conditions of the intestines, in which cases the abscess is likely to be solitary; or it may accompany a septicæmia originating in the abdominal cavity from some local disease like appendicitis or puerperal infection, in which case multiple small abscesses are found throughout the substance of the liver. Another variety of multiple abscess is that in which obstructions of the biliary ducts by gallstones occasions retentions of bile and the formation of local foci of suppuration.

Abscess is more common in tropical countries, probably on account of the greater frequency of dysentery in such localities. The direct cause of this form of abscess is probably the *Amœba coli* which bears a causative relation to certain forms of tropical dysentery.

Pathological Anatomy and Symptoms.—The liver is enlarged, and sometimes a projecting mass can be seen in the upper right portion of the abdomen. The abscess may be of small size, but frequently reaches very considerable proportions, containing perhaps a pint or more of thick pus. It may discharge externally through the skin, into the abdominal cavity or some of the abdominal organs, and even through the diaphragm, into the lung and bronchi. Occasionally a spontaneous cure results in this way. More commonly the patient perishes before the abscess ruptures, from general infection or from prostration. The disease is frequently attended with great pain, with jaundice and with irregular fever.

Treatment.—The only effective treatment of abscess is surgical operation.

Tumors.—Among the tumors of the liver, the most important is cancer. This is usually secondary to cancer of the stomach or intestines. It may, however, be primary in the liver. The liver is found enlarged and its surface irregularly studded with nodules varying in size from that of a pea to that of an apple, or even larger masses. The cancerous nodules are of white or pinkish color and the liver substance between them is usually more or less compressed and pigmented.

Symptoms.—The important symptoms are profound disturbance of general health with emaciation, such as characterize cancer in any part of the body; pain in the region of the liver, and increase in the size of the organ; jaundice of intense and lasting character; and occasionally dropsy of the abdominal cavity.

Parasitic Diseases.—The most important of these is the *hydatid cyst*, which results from the lodgment of the embryo of the *Tenia echinococcus*, a tapeworm occurring in the adult state in the intestines of dogs and some other animals. In man the larval condition alone is met with. The embryo in the liver becomes surrounded by a capsule in which a light liquid collects and thus a cyst is formed. Secondary cysts (daughter-cysts) may develop within the original one and thus a large cavity filled with smaller spherical cysts may result. The liver increases in size and the cyst may be visible, or it may be felt through the abdominal walls as a resilient projecting mass. The hydatid cyst may subsequently contract by absorption of its liquid contents or it may rupture in the same manner as an abscess. The symptoms of this disease are frequently obscure, but jaundice (from pressure

on the bile ducts), dropsy of the abdominal cavity from pressure on the portal vein, and other "mechanical" symptoms may occur.

Jaundice.—The important functional disturbance of the liver is jaundice. This condition is one in which the biliary coloring matter is absorbed by the blood and deposited in the tissues of the body. The causes of jaundice are very numerous. The condition may result from any cause of obstruction of the outflow of the bile through the biliary ducts or from any serious disease of the liver substance, such as abscess, cancer, acute yellow atrophy, etc. Various poisons and infectious diseases cause jaundice by their destructive action on the liver.

The most frequent form of jaundice is that known as *simple catarrhal jaundice*, which results from digestive disturbances, especially such as follow great excess in eating or drinking and exposure to cold. In this variety, the outflow of the bile is impeded by swelling of the mucous membrane of the duodenum where the common bile duct discharges, and also by swelling of the lining membrane of the larger bile ducts themselves. When the bile formed within the liver cannot find normal discharge, it is absorbed into the blood, and finding its way to various parts of the body, discolors these, causing the yellow appearance of the skin and mucous membranes which characterizes the disease. The bile may be in part discharged from the body through the urine, and even in the sweat, tears, and other liquid discharges.

Symptoms.—The symptoms of catarrhal jaundice are, in the first place, those of intense disturbances of digestion, such as great pain in the region of the stomach, nausea, and vomiting; later, the appearance of a yellowish discoloration of the skin and mucous membranes. The faeces become light-colored from the absence of biliary coloring matter, and in advanced cases they are actually a light clay color or even white. The urine becomes dark brown or greenish in color. The patient is depressed, often even melancholy. The pulse is slow; the temperature as a rule is depressed, though there may be a moderate degree of fever.

Treatment.—Careful dieting is an essential in the treatment. The patient must abstain from food entirely at first, and later take the less irritating of foods, such as milk, broths, and the like. Remedies, like bismuth, pepsin, small doses of calomel, and salines are administered to improve the state of digestion and lessen the congested condition of the stomach and duodenum. Drastic purgatives are harmful. Warm applications over the region of the liver are efficacious. The disease usually subsides in a few days or in a week or two.

Gall-stones.—Gall-stones are usually formed within the gall-bladder. Very rarely they may originate in the biliary ducts within the liver. They result from inspissation of the bile and inflammatory conditions in which exfoliated epithelial cells or mucus in the gall-bladder or biliary ducts accumulate and form a basis for concretion of thickened bile. The gall-stone consists of biliary pigment matters, but in some cases almost wholly of one of the constituents of bile, cholesterol. On section through a gall-stone, a central nucleus may be seen which is composed of epithelial detritus and inspissated mucus, together with bacteria in many cases.

LIVER-FLUKE — LIVERPOOL

Around this is deposited cholesterol or biliary pigment. The gall-bladder may contain a single stone or, more commonly, a number, and sometimes even hundreds are found.

Gall-stones are more common in women past middle life than in younger persons or in the male sex.

Symptoms may be wanting until a stone enters the cystic duct and becomes lodged in the latter, or passing through this, becomes obstructed in the common bile duct. The symptoms of such a passage of gall-stone are known as biliary colic. The patient is seized with intense pain, radiating to the right and to the back, sometimes as high as the right shoulder. Vomiting and other reflex disturbances and even collapse may occur. When the stone lodges, jaundice is the most pronounced symptom. Frequently the gall-stone passes with some effort and the paroxysm is relieved. Sometimes this relief is brought about by a recession of the stone into the gall-bladder.

Treatment.—The treatment of gall-stone consists of careful diet and the use of saline waters to improve the digestive conditions and render the bile as liquid as possible. Gall-stones may thus be diminished in size and enabled to pass through the ducts. During the paroxysm of biliary colic, remedies to relieve pain are imperatively necessary. Hypodermic injections of morphine and even narcosis with ether or chloroform may be required. Surgical operation for removal of the stone is often desirable.

Liver-fluke. See DISTOMA; TREMATODA.

Liver-leaf, or Noble Liverwort. See HEPATICA.

Liv'ermore, Mary Ashton Rice, American reformer and lecturer: b. Boston, Mass., 19 Dec. 1821. She was married in 1845 to Rev. D. P. Livermore, a Universalist minister (d. 1899), and was early in life active in the anti-slavery and temperance movements. In 1862 she was appointed agent of the Northwestern branch of the United States Sanitary Commission at Chicago and since the Civil War period has been conspicuous in her efforts to promote the woman suffrage and temperance movements. She is the president of the Massachusetts Woman's Suffrage Association and was for 10 years president of the Massachusetts Woman's Christian Temperance Union. Among her popular lectures are: 'What Shall We Do with Our Daughters?'; 'Women of the War'; 'The Moral Heroism of the Temperance Reform.' She is the author of 'Pen Pictures' (1865); 'Thirty Years Too Late' (1878); 'My Story of the War' (1888); 'The Story of My Life' (1897); etc.

Liv'erpooL, England, a seaport city and civic county, in Lancashire, on the Mersey estuary, about four miles from its mouth on the Irish Sea, and 185 miles northwest of London. After London it is the largest city and most important commercial port of the British empire, and in the number of its shipping and its aggregate tonnage is the first in the world. The city, irregularly built, extends for six miles along the level ground of the dock and wharf-lined east bank of the river, and in a semicircle climbs the undulating slopes in the vicinity, the highest point of which rises 230 feet above the river. During the latter quarter of the 19th century, the demolition of old houses, the erection

of vast warehouses and office buildings, the formation of new streets and the widening of old ones, have completely modernized the city. The modern public buildings are magnificent, while the new commercial buildings generally are of ornate classic design. Among the principal buildings are the town hall; the quadrangular building of the municipal offices 226 feet by 195 feet, centrally situated, with a conspicuous feature in its clock-tower and spire 200 feet high; St. George's Hall, a sumptuous building in the Corinthian style externally and internally, 420 feet long, with a colonnade of 16 columns, 200 feet long; the revenue buildings covering an area of 6,700 square yards, with a length of 467 feet, 67 feet high, and accommodating the inland revenue offices, posts and telegraphs, and the Mersey Dock and Harbor Board; the new Exchange in Italo-French Renaissance, with a frontage of 1,500 feet, lavishly decorated; and the free public library and museum, the gift of Sir William Brown, a local merchant, a handsome building of Corinthian order. One portion of the building is a reference library, with 120,000 volumes; the other section is the museum, containing departments of natural history and of antiquities. To the east of the library and museum another citizen, Sir Andrew Barclay Walker, has erected a public gallery of art, a splendid structure richly furnished with paintings and sculpture presented by other wealthy patrons of the arts, or purchased by the corporation. Between the museum and the art gallery the town council has erected as an addition to the library a public reading room, called the Picton reading room. In connection with the reference library there are six lending libraries in various parts of the city.

Other structures include many splendid piles of commercial buildings, banks, and charitable institutions. Those associated with maritime vocations are especially conspicuous and useful. Several new hotels have been built of great size and architectural splendor. The provision markets are spacious, airy, covered buildings, and are five in number. The Haymarket is an area of about 15,000 superficial yards, nearly half of which is roofed. Among the places of worship are St. Catherine's, St. Michael's, St. Nicholas', St. Luke's, the Church for the Blind, Great George Street Chapel, Hope Street Unitarian Chapel, St. Francis Xavier's, and St. Mary's Roman Catholic chapels, St. Andrew's Scotch Church, and Sefton Park Presbyterian Church. When Liverpool was constituted a bishop's see in 1880, the parish church of St. Peter was made the cathedral, but a new cathedral is building, many liberal contributions having been made for the purpose.

Among the charitable and benevolent institutions are the royal infirmary, children's infirmary, Northern and Southern hospitals, lying-in institutions, dispensaries, etc., public disinfecting establishments, and public baths. There are also various orphanages, refuges for the destitute, and institutions for the relief of every form of human suffering. The educational institutions include the University College, Royal Institution, the Liverpool Institute, Liverpool College, school of art and gallery of art. The University College (for which a fine building has been erected) is one of those belonging to the Victoria University; it has a department of

LIVERPOOL

language, science, etc., and a medical department. Besides the great educational machinery erected by the school board, private schools are numerous.

Liverpool is deficient in squares and open spaces within the city boundary, there being only three of any pretensions, but it is provided with an unusual number of public parks on the margin of the populous districts. These have been mostly provided by the corporation out of the rates, and they form a cordon around the town, available to the inhabitants of each quarter. Stanley Park (100 acres) in the north of the town is well-laid out and picturesquely planted. Sefton Park, of 375 acres, is at the extreme south of the town. The ground is naturally broken into hill and hollow, the heights affording beautiful views; about 269 acres are reserved for the park, the remainder being appropriated to villa sites. The adjuncts of the park embrace a "Rotten Row" and carriage drives, botanical gardens, lakes, cascades with rock work, pavilions, and other ornamental buildings, a conservatory, fountains, etc. The total area of public parks and pleasure grounds under the control of the corporation is 772½ acres, costing in land and works about \$4,000,000. Of the public cemeteries the most considerable are those of the parish of Liverpool at Anfield, the Toxteth cemetery, Kirkdale, Fazakerley, and West Derby cemeteries. Liverpool is well supplied with water. Local wells furnish part, and part comes from the reservoirs in the hilly district between Bolton and Blackburn, distant from Liverpool 25 to 35 miles. From the collecting reservoirs at Rivington the water, after being filtered, is conveyed to the distributing reservoirs in town, the average quantity distributed daily being about 20,000,000 gallons, and the population supplied, about 850,000. An additional supply of water from the Vyrnwy in North Wales, the works for which were completed in 1892, yield a daily supply of about 50,000,000 gallons. This enterprise included the formation of Lake Vyrnwy, an artificial sheet of water five miles long, contained within a great dam or embankment 60 feet high across the Vyrnwy.

Liverpool is the chief outlet for the manufactures of Lancashire, West Yorkshire, and Staffordshire, and carries on an immense export and import trade, especially with the United States. It possesses a magnificent series of docks and basins, and other requisites of a great seaport. The Mersey Dock Estate, on the right or Liverpool bank of the Mersey, extending in an unbroken line for about 7 miles, since 1893 is traversed throughout by an overhead electric trolley line. The river wall from the northern boundary of the Dock Estate to Herculaneum graving docks is over 6 miles in length. There are 53 wet docks and half-tide docks, among the largest of which are the Alexandria, Brunswick, Canada, Hornby, Huskisson, Langton, Prince's, Queen's, and Toxteth. There are numerous graving docks for the repair of iron and wooden vessels, and gridirons for their casual overhaul. The most modern of the graving docks, that at Canada Dock, is among the largest in the world, its length being 925½ feet, and width of entrance 94 feet. The total water area and quay space of the Liverpool and Birkenhead

docks and basins is 550 acres, of which 385 are on the Liverpool side.

On the margins of the docks are gigantic warehouses. The quays are abundantly furnished with railway lines and every other mechanical appliance for expediting the transport of goods and economizing labor.

One of the principal river features is the floating landing-stage moored off the Prince's and George's docks, in the heart of the town. This magnificent structure, supported on iron pontoons, rising and falling with the tide, and connected with the river wall by bridges of easy gradient, is an effective engineering device to meet the tidal conditions obtaining on the Mersey, where spring tides present a difference in level between high and low water of over 30 feet, and even neap tides have a range of 13 feet. The first small stage was built in 1847, a much larger was destroyed by fire in 1874; the present stage, as enlarged in 1896, has a length of 2,463 feet, and a width of about 80 feet. The great Atlantic liners come alongside the stage, and lie there for such time as may be necessary to receive and discharge passengers and mails, for all which traffic the Riverside station, specially constructed alongside the stage, offers a most convenient railway terminus. A great coasting passenger traffic is also centred at the landing-stage, and in the summer especially the traffic to the Isle of Man and ports on the coast of North Wales reaches immense proportions. The southern end of the stage is appropriated to passenger and freight ferry traffic between Liverpool and Birkenhead, Seacombe, New Brighton, and other suburban centres of population and recreation on the opposite bank of the Mersey. At the northern end of the stage a fixed jetty supplements its accommodation, and is more particularly used for the landing of cattle, chiefly from Ireland. In 1900 the number of vessels entered at the port of Liverpool was 20,300 of 9,315,674 tons (4,107 of 621,493 tons sailing vessels, and 16,193 of 8,694,181 tons steamers), the number cleared 19,670 of 9,158,332 tons. The total tonnage entered from foreign and colonial ports was 6,001,563; cleared for these ports 5,666,145. The shipping registered as belonging to the port on 31 Dec. 1900 was 1,018 sailing vessels, with an aggregate burden of 614,968 tons, and 1,073 steamers of 1,713,506 tons; total, 2,091 vessels of 2,328,474 tons.

Among the imports into Liverpool, cotton holds the chief place, the quantity imported in 1900 being valued at \$155,908,000, the total quantity imported into the kingdom being valued at \$204,912,970. Immense quantities of wheat, flour, maize, etc., are also imported mainly from North America. Live cattle and fresh meat also form leading imports. To prevent the spread of disease, the former are dealt with at the Foreign Animals' Wharf at Birkenhead, where over 20 acres of ground are devoted to this purpose, and quarters capable of accommodating 7,600 head of cattle and 16,000 sheep at one time are provided, together with slaughter houses, chill-rooms for cooling the meat to allow of its transfer to the country, and other conveniences in suitable proportion. The average number of cattle dealt with in one year is about 250,000, and of sheep 350,000.

Other extensive imports are provisions, sugar, fruits, hides, palm and olive oil, wine and spir-

LIVERPOOL—LIVINGSTON

its, timber, tobacco, and wool. Cotton manufactures are the chief export, others are metals and articles in metal, machinery, woolens, etc. The value of the foreign and colonial merchandise imported in 1900 was \$623,567,000, of the home and foreign produce exported, \$512,864,000; amount of customs revenue, \$20,873,900. The manufactures and other industries of Liverpool are varied, among them being hemp and wire rope making, sail making, iron forging, anchor and chain cable making, iron and brass founding, the making of steam-engines and other machinery, sugar refining, soap making, alkali making, etc. The manufacture of watches and chronometers is extensive. There are many large steam mills for grinding corn, rice, colors, dyewoods, etc. Ship-building is carried on to a small extent.

Four lines of railroad enter the city, namely the London & Northwestern railway; the Lancashire & Yorkshire; the Midland, Great Northern & Great Central, and the Great Western, to Birkenhead, and thence to Liverpool by ferry boats or by the Mersey Tunnel railway, a great work opened for traffic in 1886, 4½ miles in length, including the approaches.

The town is divided into 29 wards, which elect each three councillors. There are 29 aldermen and a lord mayor. The borough sends nine members to Parliament.

Liverpool is comparatively of recent growth. A castle was built here by Roger de Poictiers, to whom William the Conqueror gave the extensive tract of land between the Mersey and the Ribble. It was a small fishing town surrounded by a high mud wall when it was besieged and taken by Prince Rupert in 1644. In 1645 the Parliament settled the mill and ferry boats on the corporation as a satisfaction for their losses. In 1709 a wet dock was constructed, the first in the kingdom. From this event dated the rapid extension of its commerce and population. In 1880 Liverpool was made the see of a bishop, and in that year a charter was granted constituting it a city. The population, which in 1801 was only 77,653, in 1891 was 517,980; and in 1901, 686,332.

Liverpool, Nova Scotia, Canada, the capital of Queen's County, a town and port of entry on the south bank of the Mersey estuary at its entrance into Liverpool Harbor, 108 miles southwest of Halifax. It has large fisheries, and some manufactures of lumber, machinery, and shoes. Pop. (1901) 1,937.

Liv'erworts, or Hepaticæ, a group of cryptogamous plants, forming one of the two divisions of the class *Bryophyta* or *Muscineæ* (moss-worts), and closely related to the true mosses (*Musci*), with which some of the species are apt to be confounded. They are either spread out in the form of a simple lobed thallus, showing differentiation into a dorsal (upper) and a ventral (lower) surface, or they are composed of a small ramified stem bearing sessile leaves in two or three ranks. Root-like bodies (rhizoids) attach the plant to its substratum. Many liverworts reproduce themselves by means of brood-cells (thallidia or gemmæ), formed asexually in cups on the surface, in leaf-margins, etc. They are also reproduced sexually by means of club-shaped antheridia, containing the male elements (antherozoids), and flask-shaped archegonia, containing each an egg-cell or

oosphere. These sexual organs occur in groups either in small depressions or special outgrowths of the thallus, or as so-called flowers at the tips of the leafy shoots, or in the axils of their leaves. The spore-capsule is formed after fertilization within the archegonium, and the spores are often provided with hygroscopic elaters which assist in their dispersal. On germination a spore produces, not the common liverwort plant, but a very small filamentous protonema. There are four families of liverworts, namely, *Ricciaceæ*, *Marchantiaceæ*, *Anthocerotaceæ*, and *Jungermanniaceæ*. The first includes the duckweed-like crystalwort (*Riccia natans*); the second the exceedingly common *Marchantia polymorpha*, formerly used as a basis for medicine for ailments of the liver (whence the name "liverwort"); and the last, which is much the largest family, comprises all the leafy, as well as some thalloid forms. The Hepaticæ are generally distributed over the world, and prefer situations similar to those occupied by the mosses. There are about 4,000 species, of which about 3,500 belong to the *Jungermanniacæ*. See authorities on cryptogamic botany, especially Cooke's 'British Hepaticæ' (1893); and Strasburger, 'Text-book of Botany' (1903).

Liv'ia, Livilla, Roman woman; d. 35 A.D. She was a granddaughter of Livia Drusilla (q.v.) by Drusilla's other son, Drusus Germanicus. She married her cousin, Drusus, a son of Tiberius, and having poisoned her husband in concert with Sejanus, died in a dungeon.

Livia Drusilla, Roman empress: b. about 56 B.C.; d. 29 A.D. She was a daughter of Livius Drusus Claudianus, and was first married to Tiberius Claudius Nero, who was the father of her sons, Tiberius and Drusus. Tiberius Nero was obliged to divorce her in order to gratify Augustus, who divorced his own wife Scribonia in order to marry her. Having no children by her, the emperor adopted her sons by her first husband, one of whom, Tiberius, became his successor.

Liv'ingston, Edward, American statesman: b. Clermont, N. Y., 26 May 1764; d. Rhinebeck, N. Y., 23 May 1836. He was graduated from the College of New Jersey in 1781, was admitted to the bar in 1785, was a New York representative in the 4th, 5th, and 6th Congresses (1795–1801), and was a leader of the opposition. In 1801 he was appointed by President Jefferson United States attorney for the New York district, and in that year became also mayor of New York. During the yellow fever epidemic in 1803 he was stricken with the disease, and during his illness \$43,666.21, for which he was responsible to the United States government, were misappropriated by his fiscal agent. He confessed judgment in favor of the United States for \$100,000, and resigned both his offices. In 1804 he began the practice of law and land speculation at New Orleans. At the time of the preparation for the battle of New Orleans, he was president of the committee of public defense, and Jackson's chief assistant. During the battle he served on Jackson's staff. In 1820 he was elected a representative to the State legislature of Louisiana, in 1823–9 represented the New Orleans district in Congress, and from 7 Dec. 1829 to 3 March 1831 was United States senator from Louisiana. In 1831 he became secretary

LIVINGSTON

of state in Jackson's cabinet. This post he resigned to become minister to France in 1833; and in 1835 he returned to the United States. He was a distinguished lawyer; and as secretary of state exercised strong influence on the administration of Jackson, whose state papers, including the Nullification proclamation of 10 Dec. 1832, are generally believed to have been written by him. Among his writings are: 'System of Penal Law for the State of Louisiana' (1826); 'System of Penal Law for the United States' (1828). His 'Complete Works on Criminal Jurisprudence' appeared in 1873. Consult the biography by Hunt (1864).

Livingston, Henry Brockholst, American jurist: b. New York 26 Nov. 1757; d. Washington, D. C., 19 March 1823. He was a son of William Livingston (q.v.), and graduated from the College of New Jersey in 1774, was commissioned a captain in the Continental army, and later became aide to Gen. Philip Schuyler in the northern department with rank of major. He was also aide to Gen. Arthur St. Clair, took part in the siege of Ticonderoga, and was present at Saratoga. Subsequently he was again with Schuyler and was promoted lieutenant-colonel. In 1779 he went to Spain as private secretary to John Jay, in 1782 on the return voyage was captured by the British, and was for a time imprisoned at New York. In 1783 he was admitted to the bar and entered practice in New York. He was judge of the New York supreme court in 1802-7, and in 1807 became associate justice of the United States Supreme Court. On the organization of the New York Historical Society in 1805 he became its 2d vice-president.

Livingston, Peter van Brugh, American merchant: b. Albany, N. Y., October 1710; d. Elizabethtown, N. J., 28 Dec. 1792. He was graduated from Yale in 1731, at New York was active in the shipping business with William Alexander, Lord Stirling, and in 1755 provided the supplies for Governor Shirley's expedition to Acadia. He was long a member of the provincial council, and in 1755-6 was a delegate to the 1st and 2d provincial congresses of New York, of the former of which he was president. In 1776-8 he was treasurer of the congress. He was prominent in most of the measures that led up to the Revolutionary War, and was referred to by John Adams as "stanch in the cause."

Livingston, Philip, American patriot: b. Albany, N. Y., 15 Jan. 1716; d. York, Pa., 12 June 1778. He was graduated from Yale in 1737, became a prosperous merchant in New York, in 1758-69 was a member of the Colonial assembly, of which he was speaker in 1768, but was unseated by the Tory majority because of his strong Whig views. In 1774-8 he represented New York in the Continental Congress, and in 1776 signed the Declaration of Independence. Subsequently he sat in the New York provincial congress, in the State assembly, and in the senate. His legislative services were many.

Livingston, Robert, English proprietor in America: b. An crum, Scotland, 13 Dec. 1654; d. Albany, N. Y., 20 April 1725. He emigrated to America in 1673, spent a part of a year at Charlestown, Massachusetts Bay, removed to Albany, N. Y., and was there in 1675-86 secretary of the commissioners who directed the affairs of Albany, Schenectady, and the region adjacent.

In 1686-1721 he held the corresponding office of town-clerk. In 1686 he received from Gov. Thomas Dongan the grant of a large tract, which comprised extensive portions of the present counties of Dutchess and Columbia, and which was confirmed by royal charter of George I. in 1715. This tract was erected into the lordship and manor of Livingston, and as Livingston Manor has since been known. Livingston was the first to obtain the means for the equipment of the expedition of Capt. William Kidd (q.v.) against the pirates. He was elected member of the assembly for Albany in 1711, and sat for his manor in 1716-25. From 1718 he was speaker.

Livingston, Robert R. (the initial R. having been assumed for purposes of distinction), American statesman, commonly known as "Chancellor Livingston": b. New York 27 Nov. 1746; d. Clermont, N. Y., 26 Feb. 1813. He was graduated from Columbia (then King's College) in 1765, was admitted to the bar in 1773, was for a brief period partner in legal practice with John Jay, in 1773-5 was recorder of New York city, lost this post through his revolutionary spirit, and in April 1775 was elected from Dutchess County to the New York State assembly. In 1776 he was sent by the assembly to the Continental Congress, where he was one of the committee of five appointed to draft the Declaration of Independence, which, however, he did not sign owing to his return to enter the provincial convention. He took his seat on 8 July 1776, and was of the committee to draw up a State constitution. Under this instrument he became the first chancellor of New York (1777-1801). He resigned from the Continental Congress in 1777, but was again one of its members in 1779-81. He was secretary for foreign affairs of the United States Confederation in 1781-3, in which post he conducted with much success the business previously entrusted to the committee of secret correspondence. As chancellor he administered the oath of office to George Washington on the latter's inauguration as first President of the United States (30 April 1789). In 1801-5 he was minister to France, in which capacity he, with James Monroe as additional plenipotentiary, concluded the treaty by which Louisiana was ceded to the United States for the sum of \$15,000,000. He became the partner of Robert Fulton (q.v.) in experiments toward the employment of steam-power in navigation; launched a boat on the Seine, but was not fully successful; and later continued the work with Fulton in the United States, where in September 1807 the Clermont made the trial trip from New York to Albany in 22 hours, the average rate of speed thus being 5 miles per hour. Livingston also introduced merino sheep into New York, made general the use of gypsum for fertilizing purposes, was the principal founder (1801) of the New York Academy of Fine Arts and its first president, and was also for a time president of the New York Society for the Promotion of Useful Arts. He was styled by Franklin the "Cicero of America." By act of Congress his statue was placed in the Capitol at Washington, as one of the two representative citizens of New York State, George Clinton being the other. He published 'Essays on Agriculture,' an 'Essay on Sheep' (1809), and some addresses. Consult the biographical sketch by De Peyster (1876).

LIVINGSTON — LIVINGSTONE

Livingston, William, American statesman: b. Albany, N. Y., 30 Nov. 1723; d. Elizabethtown, N. J., 25 July 1790. He was graduated from Yale in 1741, was admitted to the bar in 1748, attained distinction in practice, was elected to the provincial legislature from Livingston manor, and in 1760 established himself at the well known country-seat of "Liberty Hall" at Elizabethtown, N. J. In 1774 he became a delegate for New Jersey province to the 1st Continental Congress, and later served in the 2d and 3d Congresses. He was a member of the committee of the 1st Congress that prepared the address to the people of Great Britain. In June 1776 he took command of the militia of New Jersey, with rank of brigadier-general, and was thereby prevented from signing the Declaration of Independence. On 28 Aug. 1776 he was elected first governor of New Jersey, and this post, having resigned his military command, he held until his death. During the first two years of his administration the State of New Jersey was perhaps more than any other exposed to the operations of the British forces, and this was the cause of many difficulties and dangers. The legislature was compelled to meet at various different places, and Tory hostility was strong against the governor, whose capture was several times attempted. In his message of 1777 to the assembly, Livingston recommended the abolition of slavery, and in 1786 caused the passage of an act forbidding the importation of slaves into New Jersey and himself liberated his two slaves. In 1787 he was appointed a delegate to the convention that framed the Constitution of the United States. He was at one time president of the "Moot," the well known lawyers' club founded at New York in 1770. He published in 1752-52 numbers of "The Independent Reflector," a weekly periodical, in which he opposed the Episcopal Church. His writings include: "Philosophic Solitude" (1747); "A Funeral Eulogium on the Rev. Aaron Burr" (1757); and "A Digest of the Laws of New York, 1691-1762" (with W. Smith, Jr., 1752-62). Consult Sedgwick, "Life and Letters of William Livingston" (1833).

Livingston, Mont., city, county-seat of Park County; on the Yellowstone River, and on the Northern Pacific railroad; about 45 miles north of the Yellowstone National Park, and 100 miles southeast of Butte. It is situated in a mining and lumbering section of the State. A branch of the Northern Pacific railroad extends from Livingston to the Yellowstone Park. It is the division headquarters for the Northern Pacific. The railroad depot cost \$75,000. Its chief manufacturing establishments are machine-shops, lime-works, railroad shops, and lumber-mills. Its trade is mainly in mining tools, wool, coke, coal, and gold, and it is a distributing centre for groceries, dry goods, and clothing for an extensive region. Livingston is a favorite resort for sportsmen, as game and fish abound. Pop. (1900) 2,778.

Livingston College, a coeducational institution founded in 1882, in Salisbury, N. C., under the auspices of the African Methodist Church. In 1903 there were connected with the school 24 instructors and 360 students. The library contains about 5,000 volumes; the buildings and grounds are valued at \$130,000; and

the productive funds \$110,000. The college course leads to the A.B. degree.

Livingston Manor, at one time a large tract of land in New York State, on the east side of the Hudson River, and the northern part of what is now Dutchess County. This land was obtained by Robert Livingston, in 1674, and comprised about 160,240 acres. The title was confirmed in 1715, and the patent obtained gave the land to the heirs forever. In 1752-4 Gov. Clinton of New York had to settle a dispute as to the eastern boundary; Massachusetts and the Livingstons both claiming the same land. The manor was divided and subdivided into holdings which are let to tenants. In 1795 the tenants made an effort to have the title pronounced invalid, but it was decreed that the land was Livingston property. In 1844 the tenants again sought to get possession, and they petitioned the Legislature to set aside the grant; but the petition was not granted. Since that time the owners have sold to individuals the larger part of the old Livingston Manor.

Livingstone, living-stōn, David, Scottish missionary and African traveler: b. Blantyre, Lanarkshire, 19 March 1813; d. near Lake Bangweolo, Africa, 1 May 1873. His parents had settled in the neighborhood of the cotton mills near Blantyre, where David became a "piecer" at the age of 10. While at work in the mill he learned Latin and read extensively, and having attended the medical and Greek classes at Glasgow University during the winter months, finally became a licentiate of the Faculty of Physicians and Surgeons of Glasgow. Under the direction of the London Missionary Society he proceeded in 1840 to South Africa, where he joined Robert Moffat in the missionary field. His first station was in the Bechuanaland territory, and here his labors for nine years were associated with Mr. Moffat, whose daughter he married. Hearing from the natives that there was a large lake north of the Kalahari desert, he proceeded to explore that region, and discovered the valley of the Zouga and Lake Ngami. Subsequently he penetrated farther northwest until he reached Linyanti, the capital of the Makololo territory, situated on the Chobe, a tributary of the Zambezi, which river he also visited. In 1853-6 he made a great exploratory journey, or series of journeys. Starting from Linyanti he ascended the Leeambye (Upper Zambezi), journeyed overland to Lake Dilolo, and thence to St. Paul de Loanda on the west coast. Returning to Linyanti, he went eastward from there in 1855, tracing the Zambezi to the Indian Ocean, and reaching Quilimane on the east coast in 1856, having thus crossed the entire continent. The record of this journey is found in his "Missionary Travels and Researches in South Africa" (1857). After making various journeys and exploring the Lake Nyassa and Zambezi region, Livingstone set forth in 1865 to set at rest the question of the sources of the Nile. From this time till his death he was engaged in laborious explorations in the lake region of South Africa, especially to the westward of Nyassa and Tanganyika, where he discovered Lakes Bangweolo and Moero, the Upper Kongo, etc. For about three years no communication had come from him, and the doubts regarding the traveler's safety were only set at rest when it was known that H. M. Stanley, the special

LIVINGSTONIA MISSION — LIVY

correspondent of the New York *Herald*, had seen and assisted Livingstone at Ujiji, on Lake Tanganyika. They parted in March 1872, Livingstone going to explore the southern end of Tanganyika, and Stanley proceeding to Zanzibar. After another year's wanderings he was attacked with dysentery near Lake Bangweolo, and there he died. His body was buried in Westminster Abbey, having been conveyed to the coast, rudely preserved in salt, by his faithful followers. Consult: 'Livingstone's Last Journals' (1874); Stanley, 'How I Found Livingstone' (1873); Blakie, 'Livingstone's Personal Life' (1880); Hughes, 'David Livingstone' (1891); Johnston, 'Livingstone and the Exploration of Central Africa' (1897); MacLachlan, 'David Livingstone,' in 'Famous Scots' Series (1900).

Livingst'nia Mission. southern Africa, established in 1875 by the Free Church of Scotland, consists of two settlements with local branches. The first settlement was made at Cape Maclear at the southern end of Lake Nyassa, but the chief settlement is at Bandawé, on the west shore of the lake. The establishment of the mission was the result of a suggestion made by Livingstone (q.v.) that the shore of this lake was a good position for a mission that might counteract the slave trade which was carried on by the Arab, and Portuguese. The Church of Scotland established a mission at Blantyre, in the Shiré Highlands, near the lake. At Blantyre some manufacturing establishments have been established, a foundry, basket factory, cloth-mill (the cloth is made from the bark of trees), and a cotton factory. The Portuguese, in 1889, tried to get possession of the territory, but since 1890 the British have had possession.

Liv'ius Andron'icus, Roman poet, by birth a Greek of Tarentum. He first went to Rome at the commencement of the 3d century B.C. as instructor to the children of Livius Salinator. He introduced upon the Roman stage dramas after the Grecian model, and, besides several epic poems, wrote a translation of the 'Odyssey' in the old Saturine verse. Only a few fragments of his writings are extant.

Livo'nia, Livland, or Riga, Russia, a Baltic province, bounded north by Estonia, west by the Baltic Sea, south by Courland, and east by Vitebsk and the Lake of Peipus; length, 178 miles; breadth, 111 miles; area, about 18,158 square miles. The surface is for the most part flat, sandy, and swampy; the only hilly ground is in the districts of Venden and Dorpat. The government is well watered by the Dwina or Duna, and Embach; its principal lakes are the Vertserf and Luban. The climate is subject to extremes of heat and cold. Notwithstanding extensive tracts of sand, the greater part of the government is under cultivation, and yields good crops of oats, barley, wheat, potatoes, flax, and hops. The forests are extensive, and furnish good timber. Horses, cattle, and sheep are generally of small inferior breeds. Distilling, sugar refining, and the manufacture of tobacco, woollens, cotton, and linen, are the chief industries. The inhabitants consist of Livonians, of Russian, Swedish and German origin, who form the landed proprietors and governing class, and are divided into the nobility and bourgeoisie; and

Estonians and Letts, who form the peasantry, and though no longer serfs (having obtained their freedom in 1824), are bound to perform certain oppressive duties for the lords of the soil. The Estonians occupy the north and east portion of Livonia; the Letts the south and west. The Estonians are of the Finnish stock (see FINNS); the Letts, like the Lithuanians, belong to the Slavonic stock, and speak a language of their own (Lettish). Of the original inhabitants of the country, the Lives or Livonians proper, who are also of Finnish race, only a thousand or two are all that are left. The inhabitants are almost all Protestants of the Augsburg Confession. The capital is Riga. Pop. (1897) 1,300,640.

Livre, lē'ver, an ancient French coin, now superseded by the franc, to which it was about equal in value.

Livy (Titus Livius), Roman historian: b. Patavium (Padua) 59 B.C.; d. there 17 B.C. He spent most of his time at Rome, but kept aloof from active political life, although among his friends were numbered the most eminent men of his day. In spite of his republican leanings, he was befriended by Augustus, who counted him with Virgil and Horace, as one of the literary ornaments of his court. His principal work is the 'History of Rome' in 142 books (*Titi Livii ab Urbe Condita Libri*), which comprehends a period extending from the building of the city to the year 9 B.C. Only 35 of these books are extant, namely the first 10, which cover the period ending 293 B.C., and the 25 from the 21st to the 45th books, which comprehend the years between 218 and 167 B.C., as well as a number of fragments, and short abstracts, or tables of contents of all the books excepting the 136th and the 137th. Livy undertook this work, as he states in his preface, partly that he might plunge his mind into things of the past, and so forget the grievances of the present, and partly that he might spread out before his contemporaries a picture of the nation's ancestral glories. He has indeed produced a work which is truly national, which has always received the admiration and esteem of antiquity, and is in modern times regarded as one of the most precious relics of Latin literature. Since his time it has been the source of all knowledge of the period it deals with. He began its composition between the years 27 B.C. and 25 B.C., and published it from time to time in a series of detached parts; the present division into decades is of later origin. It appears that he was engaged upon his history up to the time of his death, but failed to carry it on to the end he had meditated, which would have included the death of Augustus. He had a practical object in view in the accomplishment of his task, but this was less to achieve a critical and scientific exploration of the past, than to produce a moving, lifelike, and readable representation of the time and country in which he lived. With this end in view he has chosen a style of his own; not the transparent splendor of Cicero, nor the condensed and epigrammatic pungency of Tacitus, nor the dilettante, though sometimes effective, archaism of Sallust. His narrative moves along with stately dignity; it teems with anecdote, and glows with patriotic emotion. He employs a phraseology remarkable for copiousness, for picturesqueness, for vivid description and occa-

LIZARD POINT—LIZARDS

sionally for an eloquence that is burnished into poetic lustre. His materials must mainly have been derived from preceding annalists, but he weaves into his work the local traditions of a mythic age, and rivals Virgil in his love for the fables of Tuscany and Latium. His account of the Punic wars he draws from Polybius. We must not, however, expect to find in his writings a clear account of the origin and development of the Roman constitution. He seems to have cared little for the study of constitutional law, and even less for that of military art. Yet his political views were very decided, and in his account of the civil war, which resulted in the downfall of the Republic, he shows himself a strong partisan of the aristocratic party, so that Augustus did not hesitate to style him a Pompeian. The historic basis for the Roman history of Livy cannot be fully understood without reading the works of Niebuhr. Livy's complete works have been published by Gronov (1679); Drakenborch (1828); Zingerle (1883); and a translation of them appears in the Bohn Library. Fügner's "Lexicon Livianum" (1889) is important in Livian literature. Consult: Niemann, "Etudes sur la Langue et Littérature de Live" (1884); Taine, "Essai sur Tite Live" (1888); Madvig, "Emendations Livianae" (1877).

Liz'ard Point, or The Lizard, England, a headland in Cornwall, forming the southernmost point of Great Britain, 24 miles southeast of Land's End, and having two lighthouses with fixed lights 224 feet above sea-level.

Lizards, animal reptiles of the order *Lacertilia* which, together with the *Ophidia* (serpents), form the higher group *Sauria*. The one important character distinguishing lizards from snakes is the fact that the mandibles of the lower jaw are solidly united in the former and not in the latter. The lizards have generally two pairs of limbs, but one or both pairs may be absent (as in the amphisbaena), and the toes may vary in number from two to five. Though the front limbs may be wanting, the pectoral arch or bones of the shoulder-girdle are still represented; but when the hinder limbs are wanting, the pelvic arch also disappears. The spine is generally elongated, and a tail of considerable length is generally present. In most *Lacertilia*, the vertebrae are either hollow in front and convex behind (procoelous), or hollow at both ends (amphicoelous), the former condition being much more common than the latter. The cervical or neck-vertebrae may be furnished with ribs, and those of the back or dorsal region generally become united to the sternum or breast-bone. In the flying-lizard or dragon some of the hinder ribs become elongated and extended to form a support for the wing-membrane, by which this lizard is enabled to sustain itself in the air. The teeth are simple in structure, are not lodged in distinct sockets, and they generally become united to the jaw-bones with age. They vary much in form, from a toad-like plumpness to the slender shape of a snake. The food of lizards is generally insects, worms, and various small animals, but some live on vegetable substances. The eyes are provided with movable eyelids, while the ear is usually to be perceived externally. The skin is generally covered with scales or horny plates, although the integument—as in the chameleons, etc.—may

be soft; and the epidermis is shed in patches annually. In their reproduction lizards never undergo any metamorphosis, and are generally oviparous, but in some the eggs are retained until they hatch within the abdomen of the mother. Salivary glands are found which in *Heloderma* act as poison glands. The lungs are thin-walled sacs, from which terminal pouches may arise. The movement of the ribs assists in respiration. The lizards are most abundant in tropical regions, but are absent only from the cooler temperate and the frigid regions of the globe.

The *Lacertilia* are divided into three sub-orders, of which the following is an outline:

Sub-order 1. *Geckones*.—*Lacertilia* with four legs, amphicoelous vertebræ and clavicles dilated ventrally. The chorda persists and grows throughout life, in the centre of and between the vertebræ; the ribs are bifurcated, and dentition is pleurodont. Some species have mechanically adhesive disks. This is a very old group, modern species existing in tropical and southern European countries. See GECKO.

Sub-order 2. *Lacertæ*.—*Lacertilia* with procoelous vertebræ and the ventral part of clavicles not dilated. Eighteen families, as follows:

1. *Agamidae*.—A family of exclusively Old World lizards, containing some 200 species, among which the Malayan dragon (q.v.), and the frill-lizard (q.v.) are remarkable species. Many have a very chameleon-like appearance and are known in India and Ceylon as blood-suckers (genus *Calotes*). The desert lizards of North Africa and southwestern Asia are mostly of this family. See AGAMA.

2. *Iguanidae*.—A large and chiefly American family with pleurodont dentition, and a short, thick, non-protractile tongue. The genus *Anolis* contains the common "chameleon" of the southeastern United States. (See ANOLIS; CHAMELEON.) *Basiliscus*, of Central America has a great, erectile vestigial crest on the back and tail. (See BASILISK.) *Iguana* (q.v.) includes large edible lizards of Central and South America. *Phrynosoma* is the genus of the "horned toad" (q.v.), common in the arid region of the Great Plains and west to California. One of the most northerly species is the large, black, fat-bodied, bud-eating lizard of the sandy plains of southern California, known locally as Alderman lizard, or by the Indian name Chuckwalla; and scientifically named *Sauromalus ater*.

3. *Xenosauridae*.—A Mexican family intermediate between the *Iguanidae* and the *Anguidæ*; represented in Africa by (4) the *Zonuridae*.

5. *Anguidæ*.—Terrestrial pleurodont lizards, with bony plates in the skin and the tail long and brittle, dwelling in Central America, Europe and India. *Ophisaurus*, the genus of the glass snakes (q.v.) of the Central States, has the limbs reduced to mere spikes. *Anguis*, the "slow-worm" (q.v.), has no limbs at all, and the eyes well developed.

6. *Helodermatidae*.—Pleurodont, poisonous lizards of New Mexico and Arizona. See GILA MONSTER. The (7) *Lanthanotidae* are Asiatic representatives of the foregoing.

8. *Varanidae*.—Pleurodont aquatic lizards of the Old World, with bifid, protractile tongue. See MONITOR LIZARDS.

9. *Xantusiidae*.—Three Central American genera.

10. *Tejidae*.—A large tropical-American fam-

LLORENTE—LLOYD'S

Llorente, Juan Antonio Don, hoo-äñ' än-tó-né-ö dón lyō-rän'tä, Spanish historian: b. Rincon de Soto, Andalusia, 30 March 1756; d. Madrid 5 Feb. 1823. He studied theology at Tarragona and Madrid, was ordained priest in 1770; was doctor in canon law, chancellor of the University of Toledo; was commissary of the Inquisition at Logrono in 1785, and general secretary of the Inquisition at Madrid in 1789. He was commissioned in 1793 to draw up plans for a general reform of the procedure of the court. His greatest work is the 'Critical History of the Spanish Inquisition' (1815-17), which, however, has no authoritative standing among scholars. He wrote also 'Memoirs Relating to the History of the Spanish Revolution' (1815-19).

Lloyd, Ioid, Charles Harford, English musician: b. Thornbury, Gloucestershire, 1849. He displayed musical talent early, and at 10 was organist of Rangeworthy Church, and after 1862 studied music with Barrett of Bristol, confining his attention almost entirely to Bach and Beethoven. He was graduated from Oxford, where he came under the influence of Stainer, and definitely determined to make music his calling. He conducted the Gloucester musical festivals of 1877 and 1880, was organist of Gloucester cathedral in 1876 and of Oxford cathedral in 1882. Since 1892 he has been precentor and musical instructor at Eton. Among important compositions of his are the cantatas of 'Hero and Leander'; 'The Song of Balder'; 'Andromeda'; 'Alcestis'; 'Song of Judgment'; 'Long-beard's Saga.' He has also written many songs and much church music.

Lloyd, Curtis Gates, American mycologist: b. Florence, Ky., 17 July 1859. One of the founders of the Lloyd Library and collector of one of the most complete mycological museums in America. He is author of a series of bulletins on 'Mycological Notes'; and co-author of 'Drugs and Medicines of North America.' Mr. Lloyd has done much toward correcting existing errors respecting mycological species.

Lloyd, David Demarest, American playwright: b. New York 1851; d. Weehawken,

Lloyd, Ioid, David Demarest, American playwright: b. New York 1851; d. Weehawken, N. J., 1889. He was a brother of H. D. Lloyd (q.v.). He was graduated at the College of New York, and became a member of the staff of the New York *Tribune*. As a correspondent at Albany in 1875 he was prominent in exposing the canal ring. He was the author of four plays: 'For Congress' (1883); 'The Woman Hater' (1885); 'The Dominie's Daughter' (1887); 'The Senator' (1889).

Lloyd, Henry Demarest, American writer on economics: b. New York 1 May 1847; d. 28 Sept. 1903. He was graduated from Columbia University; lectured on political economy in New York schools; studied law, and was admitted to the bar in 1869. In 1872 he went to Chicago, where he was employed on the Chicago *Tribune* till 1885, the latter part of the time as a member of the editorial staff. His later life was devoted to writing. His publications include: 'A Strike of Millionaires against Miners, the Story of Spring Valley' (1890); 'Wealth against Commonwealth' (1894), a history of the growth and methods of the Standard Oil Company; 'Labor Copartnership' (1899), notes of visits to various co-operative shops and farms in Great Britain; 'A Country without Strikes'

(1900), an account of the history and workings of compulsory arbitration in New Zealand; and 'Newest England' (1900). He made the labor question his special field of research, and was an advocate of co-operation and a believer in socialistic—or, as he called it, democratic—control of industry, to which he maintained that social evolution was leading. He possessed the power of presenting economic facts in an unusually interesting manner, especially his 'Wealth against Commonwealth,' though compiled from court records and other official documents, is written with a force and vividness which give it real literary quality.

Lloyd, John Uri, American chemist and author: b. West Bloomfield, N. Y., 19 April 1849. He was educated in private schools; became professor of pharmacy at the Cincinnati College of Pharmacy, and held that position till 1887. He has been professor of chemistry in the Eclectic Medical Institute since 1878, and is now its president; and is associate editor of the 'Pharmaceutical Review,' the 'Eclectic Medical Journal,' and the 'Medical Gleaner.' He has made special studies in the dialect, superstitions, and folk-lore of northern Kentucky, is a member of many societies, contributor to chemical and pharmaceutical journals, and has written: 'Chemistry of Medicine' (1881); 'Etidorpha, the End of the Earth' (1895); 'The Right Side of the Car' (1897); 'Stringtown on the Pike' (1900); 'Warwick of the Knobs' (1901); 'Red Head' (1903); and, in collaboration, 'Drugs and Medicines of North America' (1884); 'King's American Dispensatory,' with King (1885-1900); 'Elixirs, their History and Preparation' (1892); 'A Study in Pharmacy' (1895).

Lloyd, Nelson McAllister, American journalist and author: b. Philadelphia 18 Dec. 1873. He was educated at the Germantown Academy, and graduated in electrical engineering at the Pennsylvania State College in 1892. Since then he has been engaged in newspaper work on the New York *Evening Sun*, of which he has been city editor since 1897. He has contributed many historical sketches and short stories to magazines, and has also published 'The Chronic Loafer' (1900); and 'A Drone and a Dreamer' (1901).

Lloyd's, an incorporated firm engaged in marine insurance in London, or otherwise connected with shipping, having rooms in the London Royal Exchange. Members are admitted by subscription, and the affairs of the institution are conducted by a committee. Reports are received daily from all foreign ports, and this information is posted in the common or merchants' room. Besides this, there are other rooms for the use of the underwriters and for ship-auctions, a library, restaurant, etc. Lloyd's list, containing shipping reports, is published daily, and various other publications relating to shipping are also issued. Lloyd's Registry is an independent association for the classification of shipping according to character and efficiency. Lloyd's Register of Shipping is issued annually, and the society maintains a large staff of surveyors, who inspect and report upon vessels both when built and afterward. Originally the London underwriters met at Lloyd's Coffee-house, hence the name.

LLOYD'S BONDS—LOBBY

Lloyd's Bonds, in England, from 1850 to 1870 a well known commercial security; mostly instruments under the seal of a railway or other such company admitting the indebtedness of the company to a specified amount, with a covenant to pay such amount with interest within a stated time. These companies had generally statutory authority to borrow only when a certain amount (usually the whole) of their capital had been subscribed and a specified portion paid up; their power of borrowing must also be exercised with the sanction of a general meeting. Such restrictions were severely felt by companies whose works were being constructed. A barrister, J. H. Lloyd, relieved the companies from this embarrassment by taking advantage of the fact that companies, though prevented in such cases from borrowing, could contract debts in any other way, and acknowledge their obligations in various forms. He introduced a form in which such acknowledgments would become almost as binding on the grantors as a statutory debenture, and so become sufficiently marketable.

Loach, lōch, a small cyprinoid fish of the genus *Cobitis*, which are favorite objects of quiet angling in Europe, and are good to eat. Loaches are closely allied to barbels.

Load Line, a line drawn upon the side of a ship to indicate when she is properly loaded, or if overloaded. This is quite essential, as many vessels are lost at sea, the result of overloading. The abbreviations used in designating the load line are as follows:

FW., fresh water load-line (steamer).
IS., summer load-line, Indian Ocean.
S., summer.
W., winter.
WNA., winter, north Atlantic.
F., fresh water sailing ships.

These marks are painted on iron or steel ships, and cut into the wood on wooden vessels.

Loadstar. See LOESTAR.

Loam, a soil which consists of a natural mixture of sand and clay (see SOILS); in founding, a mixture of sand and clay with straw, sawdust, etc. (called casting-loam), usually made by mixing the requisite materials in a mill similar to a pug-mill. In molding, it is used wet, like plaster, but is dried perfectly before pouring. It must be plastic while wet, and must have strength and solidity when dry, with power to resist high temperatures.

Loan, anything lent or given to another on condition of return or payment. In law loans are considered to be of two kinds—*mutuum* and *commodate*; the former term being applied to the loan of such articles as are consumed in the use, as provisions or money; the latter to the loan of such articles as must be individually returned to the lender. The acknowledgment of a loan of money may be made by giving a bond, a promissory note, or an I. O. U. (q.v.).

Loanda, St. Paul de. See ST. PAUL DE LOANDA.

Loango, lō-äng'gō, Africa, a maritime country in the southwest, extending along the Atlantic from the equator south to the river Kongo, and belonging chiefly to France, with parts to Portugal and the Kongo State. The hills are covered with luxuriant vegetation. The lakes and rivers abound with fish, and the forests with game. The finest fruits grow wild,

and the sugarcane attains an enormous size. Palm-trees are numerous, and the potato and yam abundant. The climate is equatorial and domestic animals do not thrive. Loango, the chief place, a French port, is a collection of huts and business buildings.

Lob-Nor, Central Asia, a lake of the Gobi Desert, in Eastern Turkestan, which receives through the river Tarim the waters of a large number of streams. It was first explored by Prjevalsky in 1877, and seems to be a flooded morass of salt and brackish water rather than a lake proper, its area and shape varying greatly at different times.

Lobby, The, a class of persons who seek to influence legislation outside of the regular legislature. The term was originally applied to the waiting-rooms of legislative halls, and then to those persons who frequented these rooms for the purpose of interviewing legislators with a view to influencing their votes. The lobby includes both those who are regularly employed in the work, and those who on particular occasions wish to promote or oppose some specific legislation. All large corporations and firms have regular paid lobbyists at Washington and at State capitals where legislation is likely to affect their interests. Women as well as men are employed as lobbyists, and are said to be very successful. The lobby is not in theory, nor necessarily in practice, a corrupting agency. It may furnish an entirely legitimate and desirable method of giving legislators necessary information in regard to certain laws; but it may also be, and often is, the means of obtaining legislation in the interests of a few without regard to the public good. The methods of the lobby differ with the character of the lobbyist and of the legislator approached. They vary from the legitimate presentation of facts and argument in regard to a law to the use of bribery, threats of preventing re-election, etc.; and include the obtaining of letters and petitions from constituents, the employment of press articles, and social attentions. The successful lobbyist must thoroughly understand the men with whom he has to deal and the methods of legislation; it has been found, therefore, that former members of the legislature make the most successful and sometimes the most dangerous lobbyists. The dangers of the lobby are due to three chief causes: (1) the large number of special and private bills, all of which can not be fully considered at the regular sessions; (2) the system of referring all bills to committees, and accepting, as a rule, the report of the committee, so that the lobbyist has practically but few men to deal with; (3) the secrecy which attends the work of the lobby, giving the public no effective means of knowing or dealing with its evils. To oppose the grosser evils of the lobby both Federal and State laws attach heavy penalties to giving or taking a bribe for legislation. Many of the States also have lessened the number of bills to be presented by forbidding in their constitutions the passing of special acts in certain cases. Massachusetts has sought to lessen the secrecy by requiring every promoter of a law in the interest of others to be registered, with the name and address of his employer and a statement of the matter on which he is employed. This law has had the effect of giving legal sanction to the lobbyist's work, improving the char-

LOBELIA—LOBSTER

acter of the lobbyists, and of lessening, though not entirely preventing, the evils attending secrecy.

Consult: Bryce, "American Commonwealth"; Bridgman, "The Lobby" (in "New England Magazine," n. s. Vol. XVI., p. 151); Tanner, "The Lobby and Public Men."

Lobe'lia, a genus of annual and perennial herbs and a few sub-shrubs of the order Lobiaceæ, closely allied to the harebells. More than 200 species are distributed throughout the temperate and tropical zones, especially in damp soils. They are characterized by alternate, usually narrow leaves and two-lipped tubular flowers (three petals forming one lip and two the other), arranged in terminal racemes. Several of the species are highly prized as garden plants, the best known being the cardinal-flower (q.v.), the great lobelia (*L. syphilitica*), both common natives in marshy grounds and along streams; *L. erinus*, a favorite African plant for edging flower beds; and *L. fulgens*, a Mexican species, which like the first named has brilliant red flowers. The other two generally have blue blossoms. They are all of simplest culture. Some species have been used in medicine, and one common species, *L. inflata*, is called Indian tobacco because its dried leaves were extensively smoked by the southern Indians, who enjoyed the narcotic effect in spite of the bitter flavor. Lobelin, lobelacrin and lobelic acid are organic derivatives.

Lobengula, lō-bēng-goo'lā, king of the Matabeles (see MATABELELAND): b. about 1833; d. 1894. He was a son of Mosilikatse, whom he succeeded in 1870. Fixing his capital at Bulawayo (q.v.), he made himself a powerful opponent of Western civilization, and prohibited his people, on pain of death, from accepting Christianity. After years of diplomatic effort, following the discovery of gold in his domains, Great Britain, by treaty in 1888, acquired suzerainty over his kingdom, and in 1890 the British South African Company obtained from him permission to settle in Mashonaland (q.v.), paying him a stipulated rent. After preparing to hold the country and work the gold mines, the company provoked the enmity of Lobengula, who began against the English a war which resulted in his disastrous defeat, after shocking slaughter of his men by Maxim guns. Bulawayo was taken, and Lobengula fled. During his flight he ambuscaded and killed Maj. Wilson and a British detachment, but the contest ended with his own death.

Lob'lolly Bay, or **Tan Bay**, an elegant pyramidal shrub or tree (*Gordonia lasianthus*) of the tea family, which covers considerable tracts of swampy coast along the Gulf of Mexico. It is a handsome tree, sometimes 50 or 60 feet tall, with evergreen leaves and large white fragrant flowers. Its bark is used in tanning.

Loboc, lō-bōk', Philippines, a pueblo of the province of Bohol, situated in the southern part of the province on the Socar-Vilar-Loay River, three miles from its outlet, and 12 miles east of Tagbilaran, the provincial capital. It is on the road leading from the coast. Pop. 10,200.

Lobos, lō'bōs, or **Seal Islands**, Peru, three islands in the Pacific, 12 miles from the mainland, so named from the Spanish *lobo*, "seal," large numbers frequenting the islands. They

were famous for their extensive deposits of guano, which have been depleted.

Lob'ster, the name of certain large crustaceans of the crab group, and especially of the genera *Homarus*, *Nephrops*, and *Palinurus*. To the first belong the common European and American lobsters (*Homarus gammarus* and *americanus*). *Nephrops* differs chiefly in possessing 19, instead of 20, pairs of gills, and its most important species is the Norwegian lobster (*N. norvegicus*). To *Palinurus* belongs the rock-lobster or marine crayfish (*P. vulgaris*) of Europe, as well as some tropical species, all of which differ from the common lobster in the absence of the large claws, while they possess long rigid antennæ and spiny shells. A large and handsome species of this group is abundant in West Indian waters.

The American lobster is found along the western Atlantic coast from Delaware to Labrador; from the shore to a depth of 100 fathoms. It is most abundant on the shores of Maine and Nova Scotia and uncommon on the New Jersey coast. Though living amid a variety of surroundings, the lobster prefers rocky bottoms, on which it reaches the greatest size and abundance, probably a direct result of a more plentiful food supply. Like many fishes, but to a much less degree, the lobster is migratory, moving into shallow water in the spring and returning to greater depths as the water grows colder in the fall. This habit, however, is very far from being universal and many lobsters remain in shallow waters throughout the year. The food of the lobster consists of all kinds of animals, both living and dead, and to a less extent of vegetable matter, the indigestible parts of which are regurgitated. At times they are cannibalistic. Although so well protected by their hard shells, powerful claws, and burrowing habits, lobsters have many enemies besides man. The most important of these are bottom-feeding fishes, such as the cod, tautog, skate and dogfish, which destroy great numbers of young lobsters when 2 to 6 inches long, as well as the egg-bearing females and moulting adults. During the free-swimming larval stages great numbers probably fall a prey to surface-feeding fishes like the menhaden and herring, though little direct proof of this exists. The number of eggs produced by a female lobster varies from 3,000 to nearly 100,000, according to the size and age of the animal, maturity being attained at an age of 3 or 4 years and a length of about 8 to 12 inches. The great majority (about four fifths) lay their eggs during the summer, the remainder during the fall and winter, and it is probable that each female lays once in two years. After extrusion the eggs are borne on the appendages attached to the lower side of the abdomen or tail of the female, where they remain undergoing a slow development for 10 or 11 months, most of those laid during the summer hatching in June of the following year. After hatching, the young passes a period of 6 to 8 weeks as a free-swimming pelagic larva, which moults 5 or 6 times, with corresponding changes in form and color. By this time it has assumed the form of the adult and is about three fourths of an inch long. It now sinks to the bottom and burrows into the gravel or hides in rock crevices near shore. At the end of the first year it is about 4 or 5 inches

LOBWORM—LOCK

long and has moulted from 14 to 17 times, after which growth is much less rapid and moulting less frequent. The rate of growth varies greatly according to the food supply and other conditions, but a lobster of 10 or 12 inches is about 5 years old. A great age and size are sometimes attained, individuals weighing upward of 40 pounds being recorded, though even 25 pounds is very rarely reached.

The toothsomeness of the American lobster was early recognized and a regular fishery has existed on the Massachusetts coast for nearly a century. Owing to a rapidly extending depletion of the fishing-grounds and a consequent diminution in the size and number of lobsters, the centre of the fishery has shifted northward, first to Maine and then to the British provinces. The lobster fisheries of the United States in 1901 employed 4,348 persons, 4,151 vessels and boats and 208,563 lobster-pots, representing an investment of \$1,668,060, nearly three fifths of which is credited to Maine. The yield was 15,767,741 pounds, valued at \$1,390,579, of which 12,346,450 pounds were taken in Maine. After about 1885 the yield declined steadily, but the value of the product increased. As measures toward maintaining the lobster supply, laws have been enacted fixing fines for the possession of egg-bearing lobsters or those below a specified minimum size, and recourse has been had to artificial propagation. In the latter practice many millions of eggs are annually taken from the bearing lobsters, artificially hatched, and the larvae distributed by the fish commissions of the United States and the British Provinces. In 1902 our Bureau planted upward of 81,000,000 of fry, and the Canadian government operates on an even more extensive scale. The beneficial results have been scarcely apparent, but the recent successful rearing of lobsters beyond the larval stages has introduced a more hopeful outlook. The methods of the lobster fishery are very simple and uniform. Use is made of a trap or pot, a box-like affair generally made of laths placed about one inch apart, and with a funnel-shaped opening of coarse netting placed in one end. The pot is baited with otherwise useless fish, weighted with stones, and lowered to the bottom by means of a rope to the upper end of which a buoy, with the owner's private mark affixed, is attached. The pots are visited daily, and the lobsters, which after entering are unable to find their way out, removed. They are kept alive in floats until a sufficient number for shipment has been gathered. Besides those sold in the shells, large quantities of the meat are canned, particularly at Portland.

Consult especially the elaborate account of the American lobster by Herrick, in 'Bulletin of the U. S. Fish Commission' for 1895, in which full bibliographical references will be found.

Lob'worm. See LUGWORM.

Local Government. See MUNICIPAL GOVERNMENT.

Local Option, or local control of the liquor traffic; a term applied to the principle by which a certain majority of the inhabitants or taxpayers of a certain locality, town, county or State, may decide as to whether any, or how many, places for the sale of intoxicating liquors shall exist in the locality. What considerations should determine a locality, who should be the

constituents, what should be the majority necessary to vote the abolition of licenses, and whether the trade thus affected should receive compensation or not, are points not as yet satisfactorily settled. This principle operates in several localities in the United States with varying success from the prohibition or temperance point of view. Local option in the States of Maine and Kansas has resulted in restricted laws governing the liquor traffic. Many small towns and villages have adopted local option with more or less satisfactory results. The words "local option" had their origin with the temperance reformers who have sought to secure power and authority enabling them to regulate the liquor traffic, either by maintaining unchanged, increasing, diminishing, or wholly suppressing the houses for the sale of intoxicating liquors.

Loch Lomond. See LOMOND, LOCH.

Lochleven. See LEVEN, LOCH.

Lock, a mechanical appliance used for fastening doors, chests, etc., generally opened by a key. The lock is reckoned the masterpiece in smithery, a great deal of art and delicacy being required in contriving and varying the wards, springs, bolts, etc., and adjusting them to the places where they are to be used, and to the several occasions of using them. The principle on which all locks depend is the application of a lever to an interior bolt, by means of a communication from without; so that, by means of the latter, the lever acts upon the bolt, and moves it in such a manner as to secure the lid or door from being opened by any pull or push from without. The security of locks in general, therefore, depends on the number of impediments we can interpose betwixt the lever (the key) and the bolt which secures the door; and these impediments are well known by the name of wards (which slip into corresponding grooves of the key), the number and intricacy of which are supposed to distinguish a good lock from a bad one. If these wards, however, do not in an effectual manner preclude the access of all other instruments besides the proper key, it is still possible for a mechanic of equal skill with the lockmaker to open it without the key, and thus to elude the labor of the other. Another kind of impediment is the tumbler, which is a small projecting piece of metal carried on a latch, and which rests in a notch cut in the bolt, and can only be raised by application of the proper key. Various complicated and difficult locks have been constructed. In a very ingenious lock, invented in England, 24 small blocks of metal, of different sizes, are introduced, corresponding to the letters of the alphabet. Out of these an indefinite number of combinations may be made. The person locking the door selects and places the blocks necessary to spell a particular word, known only to himself; the act of locking or throwing out the bolt produces the particular arrangements in the internal parts of the lock, and no other person, even if in possession of the key, can open the door without a knowledge of the same word.

The padlock, in which the lock is a separate arrangement, is precisely similar to other locks except in shape. It has also a movable bow which is hooked into a staple or other fastening and then locked. Locks for drawers, cupboards, and the like, which only require to be opened on one side, are generally made with a central pin

LOCK HAVEN—LOCKE

on which the key, with a pipe, works; but in locks which must be opened from both sides this arrangement is impossible, and the key is solid, working through a hole in the lock. It must, however, be symmetrical, so as to exactly reach the turning place of the lock from either side. Locks which are mortised into the thickness of the door are called mortise locks. Many ingenious automatic latches have been invented for cabinets and the like, which shut of themselves when the door is closed, and can be pulled open without a key or turning a handle; they are used when security is not required, only a means of keeping the door closed.

For Lock in firearms, see MUSKET; REVOLVER; RIFLE.

Lock Haven, Pa., city, county-seat of Clinton County; on the Susquehanna River and on branches of the Beech Creek and the Pennsylvania R.R.'s; about 68 miles northwest of Harrisburg. The first settlement was made in 1769 and, in 1833, it was incorporated as a town. In 1844 it was made a borough, and in 1870 received its city charter. It is situated in an agricultural and lumbering region. Its chief industrial establishments are lumber and planing-mills, tanneries, cigar-box factory, cigar factory, foundries, sewer-pipe works, fire-brick works, silk-mill, breweries, paper-mill, and furniture factory. The State Central Normal School is situated here. Some of the prominent buildings are the court-house, a hospital, and several of the churches. The city has a circulating library containing about 6,000 volumes. Pop. (1900) 7,210.

Locke, Lök, David Ross ("PETROLEUM V. NASBY"), American humorist and satirist: b. Vestal, Broome County, N. Y., 20 Sept. 1833; d. Toledo, Ohio, 15 Feb. 1888. He learned the trade of printer and after being connected with several newspapers was editor and owner of the Toledo *Blade* in 1865, and very soon became popular as a humorous writer and later as a lecturer. He began his "Nasby" letters in the Findlay "Jeffersonian" in 1860 and continued them throughout the Civil War. They exercised much influence in molding popular opinion, upholding as they did the policy of the Lincoln administration. In later years the satire of the letters, which still continued to appear, was aimed at President Johnson and his peculiar methods. They were collected and published in book form under the titles "Divers Views, Opinions, and Prophecies of Yours Truly" (1865); "Swingin' Round the Kirkle" (1866); "Ekkoes from Kentucky" (1867); "The Struggles—Social, Financial, and Political—of P. V. Nasby" (1872). He also published "Hannah Jane"; "The Moral History of America's Life Struggle"; "The Morals of Abou Ben Adhem."

Locke, John, English philosopher: b. Wrington, Somerset, 29 Aug. 1632; d. Oates, Essex, 28 Oct. 1704. He was the son of an attorney who was also a captain in the Parliamentary army. Locke was educated at Westminster School and at Christ Church, Oxford, where he was graduated and took his bachelor's degree in 1656, two years later took the degree of M. A., and entered upon the study of medicine. He lectured at Oxford (1661-4) on Greek, rhetoric, and philosophy, and during this period became interested in experimental phys-

ics, especially chemistry and meteorology, and in metaphysics showed a preference for studying Descartes, although his own philosophy powerfully antagonizes that of the French master. Theology and politics, including diplomacy, also engaged his attention. At Oxford before 1666 he is said to have practised medicine, in which, however, he was never graduated. As secretary to Sir Walter Vane, British envoy, he went in 1665 to Cleves, Prussia, returning to Oxford in the following year, during which time he made the acquaintance of Lord Ashley, afterward 1st Earl of Shaftesbury, became his family physician and secretary, under his patronage held various offices, and in 1682 accompanied him in his retirement to Holland. Locke continued to reside abroad until 1689, when the revolution had been accomplished, then returned to become commissioner of appeals. His association with Lord Ashley, between whom and himself there was close intellectual sympathy, was stimulating to his genius, and it was in Ashley's house that Locke first planned the "Essay on the Human Understanding." Fully elaborating this work during his voluntary exile, he published it in complete form in 1690, with a dedication to the Earl of Pembroke, whose acquaintance he had made at Montpellier many years before. The "Essay," which had largely occupied him for almost 20 years, met with much objection in England, being particularly opposed at Oxford; but on the Continent it brought him great celebrity, and was translated into French and Latin, and later into other languages. For the copyright of the first edition he received but £30, and although he had previously published two works this was the first to bear the author's name. In 1695 Locke was made a commissioner of trade and plantations, but in a few years became incapacitated and retired, and from 1700 until his death lived with his friend, Sir F. Masham, at Oates. Meanwhile being drawn into the violent controversies over the essay which arose among different sects and schools, he had sturdily maintained his ground in a style of epistolary polemics which still possesses an academic interest.

As a philosopher Locke's place is usually fixed at the head of the English Sensational School, although this classification by no means does justice to his many-sidedness as a thinker, and the term "sensationalism," with its ordinary connotations, is wholly inadequate for a correct representation either of his speculative inquiries or of those still less definable meditations which led him profoundly to search the realms of ethics and of spiritual laws, in an endeavor to assign the relations and functions of these in the world of practical politics and that of instituted religion. Of that sensationalist school of which he is reputed to have been founder, it has been said with much pertinence that its ultimate conclusions are such as "his calm and pious mind would have indignantly repudiated." The "Essay on the Human Understanding" holds a permanent place among the greater works of philosophy, in the history of which, however, Locke's method may be superseded, and although his main doctrine be exploded, the book retains its importance as an epoch-marking achievement. It seeks the primal sources and the scope of human knowledge, denying the existence of innate ideas, presenting the mind as a sheet of white paper prepared to

LOCKE — LOCKPORT

be written upon by experience, which alone supplies the knowledge there impressed, and tracing the sources of all ideas to what he calls sensation and reflection. This doctrine of the *tabula rasa* or white paper found a vigorous controverter in Leibnitz (q.v.). The opposition which Locke thus represented between all intuitional and experiential philosophies still remains a central point of dispute among thinkers of various schools, but he was a forerunner in psychology, as he was also in the advocacy of civil and religious liberty, for which he suffered persecution and betook himself to exile.

Upon questions of government Locke was in the main a follower of Hobbes (q.v.) in so far as the latter regarded governmental authority as something delegated by the subjects for the creation of the state, through a compact which carried in itself the principle of obligation. But he went far beyond Hobbes in the application of his views to the concrete affairs of politics. In 1689 a constitution for the Carolina colonists was drafted by him, and was an evidence of his concern to put political philosophy to practical service. Besides the 'Essay,' his works include letters 'Concerning Toleration' (1689); 'Two Treatises on Government' (1690); 'Some Thoughts Concerning Education' (1693); 'The Reasonableness of Christianity'; and a little book 'On the Conduct of the Understanding,' posthumously published. Frazer's edition of the 'Essay' (1894) is the most desirable. His philosophical writings have been published in various editions, Saint John's (1854 et seq.) being one of the most useful. Consult: King, 'The Life of John Locke' (1829); Fox Bourne, 'The Life of John Locke' (1876); Fowler, 'John Locke' (1880); Frazer, 'Locke' (1890); Russell, 'The Philosophy of Locke' (1891); and Ueberweg-Heimze, 'Grundriss der Geschichte der Philosophie' (8th ed., 1896), where a more extended bibliography is to be found.

Locke, William John, English novelist: b. 20 March 1863. He was educated at Queen's Royal College, Trinidad, and Cambridge University, and is now (1903) secretary of the Royal Institute of British Architects. His fictions include 'At the Gate of Samaria' (1895); 'The Demagogue and Lady Phayre' (1896); 'A Study in Shadows' (1896); 'Dereelicts' (1897); 'Idols' (1898); 'The White Dove' (1900); 'The Usurper.' These have been reissued in the United States. He has also written two plays, 'Mr. Cynic,' played in 1899, and 'The Lost Legion' (1900).

Lock'er-Lamp'son, Frederick, English lyric poet: b. Greenwich 29 May 1821; d. Rowfant, England, 30 May 1895. He wrote a volume of "society verses" greatly admired for their grace and finish, 'London Lyrics' (1857); edited an anthology, 'Lyra Elegantiarum' (1867); and wrote a collection of miscellanies entitled 'Patchwork' (1879). In 1874 he married for his second wife the daughter of Sir Curtis Lampson and took her name in addition to his own. Consult 'My Confidences,' his autobiography (1896).

Lockhart, lök'ärt, John Gibson, Scottish editor and biographer: b. Cambusnethan, Lanarkshire, 14 July 1794; d. Abbotsford 25 Nov. 1854. He was graduated at Glasgow and Oxford universities and became a member of the

Scottish bar. He never practised as an advocate, but devoted his time to literary pursuits. In 1817, with Professor Wilson, he established 'Blackwood's Magazine,' a Tory organ, which at the outset created an immense sensation by the ability and keen satire displayed in many of its articles. In 1820 Lockhart, who had previously become a favorite with Sir Walter Scott, married his eldest daughter, and much of his future life took its color from this connection. In 1826 he succeeded Gifford in the editorship of the 'Quarterly Review,' and continued in the position till 1853. His translations of 'Spanish Ballads,' originally contributed to 'Blackwood,' were collected in 1823. He also published the novel 'Valerius' (1821); 'Reginald Dalton' (1823); 'Adam Blair' (1822); and 'Matthew Wald' (1824); 'Life of Robert Burns' (1828); 'Life of Sir Walter Scott' (1839-41). This last, though indebted for much of its interest to its subject, is on the whole written, notwithstanding occasional prolixity, with taste and judgment. Lockhart, for his steady attachment and important services to the Conservative party, was rewarded in 1843, by Sir Robert Peel, with the appointment of auditor of the duchy of Lancaster. He was buried in Dryburgh Abbey, close by Sir Walter Scott. Consult: Lang, 'Life of John Gibson Lockhart' (1896).

Lockhart, lök'härt, Texas, town, county-seat of Caldwell County; on the Missouri, K. & T., and the San Antonio & A. P. R.R.'s; about 28 miles south of Austin and 140 miles west of Houston. It is situated in a fertile agricultural section in which cotton and live-stock are raised extensively. Some of its industrial establishments are a soap-factory, cotton-gins, cottonseed-oil mill, wagon and carriage factory, cotton-compress, stock-yards, grain-elevators, and lumber-yards. Pop. (1900) 2,306.

Lockjaw. See **TETANUS**.

Lock'out, the discharge and keeping out of employment of artisans and laborers by their employers. It is a retaliatory measure adopted by some capitalists to resist the demands for shorter hours, more pay, etc., made by their workmen. The workmen may themselves be responsible for a lockout, just as an employer may be responsible for a strike upon the part of his workmen. See also **STRIKES**.

Lock'port, N. Y., city, county-seat of Niagara County; on the Erie Canal, and on the Erie, the Buffalo & L., and the New York C. R.R.'s; 12 miles from Lake Ontario, 20 miles east of Niagara Falls, and about 25 miles north by east of Buffalo. It was settled in 1823 by workmen who were employed on the Erie Canal. On 26 March 1829 it was incorporated as a village, and became a city 11 April 1865. It is situated in a fertile agricultural region; but the extensive water-power obtained from the canal has made it an important manufacturing city. The 10 large locks of the canal, which here make a descent of 66 feet, have given name to the city. The canal passes through a deep cut, an excavation in the solid rock, several miles in length. The New York Central Railroad bridge, 500 feet long, crosses the canal here, at a height of 60 feet above water. There are large sandstone and limestone quarries in the vicinity.

LOCKROY—LOCKYER

The chief manufactures are pulp and paper, Holly waterworks machinery, wood-work machinery, machinery for flour mills, glass, rolling-mill products, cotton-batting, wagons and carriages, brooms, flour, indurated fibre, aluminum, cotton and woolen goods, and creamery products. Lockport has 20 large manufacturing establishments, which have nearly 12,000 employees. In addition to the trade in manufactured articles, the city has an extensive trade in the quarry products, and in grain and fruits. It has (1903) four banks, with a combined capital of \$3,500,000. Some of the prominent buildings are the high school, the new government building, and the court-house. It has 19 churches and good public and parish schools. It is the seat of Saint Joseph's Academy. The city owns and operates the waterworks. The government is vested in a mayor and a council of 10 members, elected annually. Pop. (1900) 16,581. Consult Pool, 'Landmarks of Niagara County.'

T. T. FEELEY,
Editor 'Review.'

Lockroy, Edouard Etienne Antoine Simon, à-doo-är à-tē-én à-n̄-twan sē-mōn lök-rwa, French journalist: b. Paris, France, 18 July 1838. He took part in Garibaldi's Sicilian expedition and was prominent as a journalist before and after the war with Germany. On account of his radical articles published in 'Figaro,' 'Le Rappel,' and 'Le Peuple Souverain,'—a popular political journal, of which he was editor,—he was imprisoned for a few months in 1872 and again in 1873. He entered the Assembly in 1873, there voting with the extreme Left. He was minister of commerce (1886-7), and of public instruction (1888). His published volumes of collected newspaper articles include: 'The Eagles of the Capitol' (1869); 'Down with Progress' (1870); 'The Commune and the Assembly' (1871); 'The Rebel Island' (1877); 'Von Moltke' (1891), memoirs; 'A Mission in the Vendée, 1793' (1893).

Locks, Canal. See CANALS.

Locksley Hall, a well-known poem by Lord Alfred Tennyson (q.v.), first published in 1842.

Lockwood, Belva Ann Bennett, American lawyer and reformer: b. Royalton, N. Y., 24 Oct. 1830. She was graduated from Genesee College, Lima, N. Y., in 1857, and taught school 1857-68. She was married in 1848 to Uriah H. McNall (d. 1853), and in 1868 to Dr. Ezekiel Lockwood. She studied law at Washington, and was admitted to the bar in the District of Columbia in 1873. Before that time she had secured the passage of a bill giving women employees of the government equal pay for equal work; in 1879 she obtained the passage of a bill permitting women to practise before the United States Supreme Court, and was admitted under this law in the same year. She has been engaged in many important law cases, some before the Supreme Court, and was one of the attorneys in the probate of the will of Myra Clarke Gaines. She has also been active in temperance, peace, and woman suffrage movements; has been secretary of the American branch of the International Peace Bureau; and in 1884 and 1888 was the nominee of the Equal Rights Party for President of the United States. In 1896 she was commissioned by the Secretary of

State to represent the United States at the Congress of Charities and Corrections in Geneva, Switzerland; in 1901 she was elected president of the Women's National Press Association. She has for several years been interested in the claims of the North Carolina Cherokee Indians, and in 1900 had a bill before Congress to prevent encroachment upon their territory. She also prepared an amendment to the Statehood Bill before Congress in 1903, granting suffrage to women in Oklahoma, Arizona, and New Mexico.

Lockwood, Henry Hayes, American soldier, tactician, and educator: b. Kent County, Del., 17 Aug. 1814; d. Washington, D. C., 7 Dec. 1899. He was graduated from West Point in 1836, served as lieutenant of the 2d artillery in the Seminole war in Florida (1837), resigned from the army and undertook agriculture in Delaware. In 1841 he became professor of mathematics in the United States navy, in 1845 of natural philosophy at the Naval Academy, where he was professor of artillery and infantry tactics in 1845-61, and of astronomy and gunnery in 1851-61. He entered the Civil War as colonel of the 1st Delaware infantry, on 8 Aug. 1861 was promoted brigadier-general of volunteers, at Gettysburg commanded a brigade of the Twelfth corps, and in 1863-4 was commander of the Middle Department. Subsequent to the war he was professor of natural philosophy at the Naval Academy, and in 1871-6 was connected with the Naval observatory. He published 'A Manual for Naval Batteries' (1852), and 'Exercises in Small Arms and Field Artillery, arranged for Naval Service' (1852).

Lockwood, Ingersoll, American author: b. New York 1841. Besides such works for juvenile readers as 'The Travels of Little Baron Trump'; 'Wonderful Deeds of Little Giant Roab'; 'Extraordinary Experiments of Little Captain Doppelkopp'; and 'Baron Trump's Journey Underground,' he has written 'Legal Don'ts'; 'Private Letters of a French Woman'; etc.

Lockwood, James Booth, American soldier and Arctic explorer: b. Annapolis, Md., 9 Oct. 1852; d. Cape Sabine, 9 April 1884. He entered the army as 2d lieutenant in 1873, and served till 1880 in the West. He volunteered to accompany the Lady Franklin Bay expedition to the Arctic regions and was made second in command. His fame rests on the discovery of Lockwood Island, in lat. 83° 24' N., the farthest northern point of land or sea up to that time. His body was brought to the United States and interred in the grounds of the Naval Academy. Consult Lanman, 'Farthest North' (1885).

Lockyer, lök'yér, Sir Joseph Norman, English astronomer: b. Rugby 17 May 1836. He was educated privately, entered the War Office in 1857, and in 1870 was appointed secretary of the royal commission on the advancement of science. Five years later he became astronomical lecturer at South Kensington, and since 1881 has been professor of astronomical physics in the Royal College of Science. He directed the eclipse expedition to Sicily in 1870, and to India in 1871, and he subsequently directed many others, including those of 1896 and 1897. In 1874 he was awarded the Rumford medal of the Royal Society, and became editor of 'Nature,' a post which he still holds, and was knighted in

LOCO-FOCOS — LOCOMOTIVE

1897. He is best known as a popular lecturer on science, and in connection with his discoveries in spectrum analysis. He has published: 'Elementary Lessons in Astronomy' (1870); 'Contributions to Solar Physics' (1873); 'The Spectroscope' (1873); 'Primer of Astronomy' (1874); 'Studies in Spectrum Analysis' (1878); 'Star-Gazing' (1878); 'Chemistry of the Sun' (1887); 'The Movements of the Earth' (1887); 'The Meteoritic Hypothesis' (1890); 'The Dawn of Astronomy' (1894); 'The Sun's Place in Nature' (1897); 'Recent and Coming Eclipses' (1897); 'Inorganic Evolution' (1900).

Loco-Fo'cos. In United States history, a political nickname applied to the equal rights or radical faction, 1835-7, of the Democratic party, properly of New York, though the name was afterward made national. During the Federalist control of the government, the method of granting bank charters and controlling banks was charged by the opposing faction with favoritism and corruption. Upon their gaining control, things did not, in the opinion of many, improve; and in 1835 there was formed in New York the "Equal Rights party," opposed to special privileges in granting bank charters to corporations. At a meeting in Tammany Hall, 29 Oct 1835, the regular Tammany Democrats tried to gain control. Finding themselves outnumbered they turned out the lights and retired. The Equal Rights men produced candles and "Loco-foco" matches, and continued the meeting. Hence the name. This party was beaten at the elections, but nevertheless exercised considerable influence in national affairs for several years. For a time the name was shortened into "locos."

Lo'co-weed, or Loco-vetch. See CRAZY WEED.

Locomo'tion, Animal. See FLIGHT; SWIMMING.

Locomotive, The. Although there were numerous predictions and suggestions of steam-propelled carriages, notably those of Sir Isaac Newton in 1680 and of others, the first locomotive that deserves the name was that of Richard Trevithick in 1803. True, Cugnot made a steam-driven road wagon in 1769 and Murdoch in 1784, but Trevithick was without doubt the father of the locomotive. He found that plain wheels had sufficient adhesion and that cogs were unnecessary; he used high pressure steam; he turned the exhaust into the stack and on discovering its effect on the fire, called it the "blast pipe." His first engine had four wheels, all drivers, 4 feet 6 inches in diameter. The boiler was 6 feet long and had a return flue, bringing the chimney or stack at the same end as the fire door. There was only one cylinder, but the length made up for two, as it was 8 inches in diameter by 54 inches long. Unfortunately circumstances prevented Trevithick from following up the development of the locomotive and as a consequence many of his ideas have been credited to others. Between Trevithick's engine and the Rocket (1829), which is sometimes called the first locomotive, men had not been idle by any means. Blenkinsop in 1812, Hedley with his Puffing Billy in 1813, Stephenson's Blucher in 1814, Oliver Evans in the same year and others make up the list.

In 1825 the first public railway was opened, the Stockton and Darlington Railway, and George Stephenson was engineer. Its first en-

gine was the Locomotive which was built by Stephenson in 1825. He also built the Hope, Black Diamond, Diligence and Experiment in 1826. Timothy Hackworth's Royal George, a rebuilt engine, went into service in 1827, but none were entirely satisfactory, and a prize of \$500 was offered in 1829 for the best engines. The Rocket, Novelty and Sanspareil entered and the Rocket won, although some claim this was due solely to the failure of the others, caused by poor work or material. This was the famous Rainhill trial which is so often quoted, and in which 29 miles per hour was made. The main dimensions of the Rocket were:

Cylinders, 8 x 16½.
One pair drivers, 3 ft. 8½ in.
Boiler, 3 ft. 4 in. diameter, by 6 ft. long.
Steam, 50 lbs.
Firebox, 3 by 2 ft.
Tubes, 23 three-inch.
Tubes H. S., 117.75.
Firebox, H. S., 20.
Total, H. S., 137.75.
Weight of engine, 4 tons 5 cwt.

This trial proved the success of the locomotive as a means of hauling loads, and this is probably the main reason that Stephenson has been given credit which belonged to others. In 1828 Horatio Allen went to England for the Delaware and Hudson Canal Co. and bought four locomotives, three from Foster, Rastrick & Co. and one from Stephenson. Stephenson's engine arrived first in January 1829 and was called the America. It had cylinders 9 by 24 inches, a boiler 49 inches in diameter by 9 feet 6 inches long with two fire tubes 19 inches in diameter. The four drivers were 48 inches in diameter, and the cylinders were at an angle of 33 degrees to the horizontal. This engine had a kind of "bar frame." Although the America arrived in the country first, it was not the first to run and for that reason the Stourbridge Lion, the first of the other three engines, is generally considered as the first engine in this country. This engine had cylinders 7½ by 36 inches. The boiler was 48 inches in diameter by 10 feet long. The reversing was accomplished by shifting eccentrics on the axle. From this date the United States began to take a hand in the development of the locomotive, and foremost at this time was the Baltimore & Ohio Railroad. On 4 Jan. 1831 they offered \$4,000 for the best American engine of 3½ tons to pull 15 tons on a level at a 15-mile speed. It must burn anthracite coal, be on four wheels and run on 400 foot radius curves, steam not to exceed 100 pounds. Phineas Davis won the prize with the York, a vertical engine with four 30 inch wheels. Ross Winans was connected with the road as engineer and this experience doubtless aided the work he did in after years as a locomotive builder of no small fame. The "Bury" boiler came into existence in 1832 in the engine Caledonian for the Liverpool and Manchester Railway. In the same year, the Ironsides, Matthew Baldwin's first engine, was put into service in this country. This was the beginning of the Baldwin Locomotive Works, the largest in the world.

The first steam whistle on record came into existence about this time, 1833, and was placed on the engine Samson, one of Stephenson's make. It is credited to a Mr. Bagster of the Leicester and Swannington Railway, on whose lines it was used.

LOCOMOTIVE

Large wheels began to be the fad and 7, 8 and even 9 foot drivers were built. The Liverpool was one of the famous Crampton engines with the drivers behind the firebox. The Cornwall was built by F. Trevithick in 1847 and had drivers 8 feet 6 inches in diameter. As originally built, this had the driving axle *above the boiler*. This was afterward changed and the engine was running the 45 minutes express between Manchester and Liverpool as late as 1897,—a remarkable length of service for a locomotive. This attained a speed of 79 miles an hour as early as 1851, while speeds of 75 miles were frequently reported. In 1853 the locomotive superintendent of the Bristol and Exeter Railway built a class of tank engines with 9 foot drivers, which seem to have capped the climax for large driving wheels. A speed of 81 miles an hour has been claimed for these engines and it is said the average consumption of coke was only $21\frac{3}{4}$ pounds per mile. The first locomotive in England to have a Giffard injector was Ramsbottom's Problem, which was built in November 1859.

Tractive Power.—Tractive power is another name for drawbar pull and shows the amount of horizontal effort exerted by a locomotive. It depends on the steam pressure, size of cylinders and diameter of drivers. The original formula or rule takes into account the area of both cylinders, circumference of wheel etc.; but this has been boiled down by cancellation to the following: Tractive power equals the square of cylinder diameter, times stroke in inches, times mean effective pressure per square inch, divided by the diameter of the driving wheel in inches. Put in the shape of a formula this is:

$$\text{Tractive power in pounds} = \frac{d^2 \times S \times P}{D}, \text{ where}$$

d = diameter of cylinder,
 S = length of stroke in inches,
 P = mean effective pressure.
 D = diameter of driving wheel.

For tractive power calculations, the mean effective pressure is generally taken as 85 per cent of the boiler pressure.

Taking the case of an 18 by 24 inch engine, 68 inch drivers, 200 pounds of steam, and we have

$$\frac{18^2 \times 24 \times 170}{68} \text{ or}$$

$$\frac{324 \times 24 \times 170}{68} = 19,440 \text{ pounds,}$$

drawbar pull, not allowing for internal friction of engine.

An easy way of reckoning is to remember that the cylinder diameter squared, equals the tractive power for one inch stroke, one pound pressure and one inch driver. Thus in the case above, if the stroke had been one inch, pressure one pound and driver one inch, the tractive power would have been 324 pounds. The actual pressure and stroke are multiplied by this and of course divided by the diameter of drivers, also in inches. From this can be readily seen how the diameter affects the tractive power and why freight engines have small drivers. If one engine has 84 inch drivers and another only 42 inches, other dimensions being the same, the latter will pull twice as much at drawbar, which means that it will start a train of double the size as the first. These calculations do not allow for internal friction.

Driving Wheels.—The number of driving wheels depends on the work to be done. A fast passenger train with few stops is often handled by an engine having but one pair of drivers in Europe and in a few instances in the United States. While the engine may slip slightly on starting, the number of starts are few and there is no friction from side rods, as in coupled engines. Every pair of wheels coupled together means added friction of the side rods, but it also means a reduction of the chance of slipping at the start. A little thought will show that the main pair of drivers are the only ones really driving the engine, unless this pair tends or starts to slip. When this occurs the others take up their share of the work. As this only occurs at the start or on a heavy grade, the extra drivers are apt to be carrying wheels only, the greater part of the time, although the heavy trains now being hauled in freight service give nearly a maximum load to the engine. For an all around engine, the American or eight wheel engine still has the lead, although most modern freight engines have six and eight drivers, while some roads are using 10 wheel passenger locomotives; the great majority, however, are still eight wheelers. The question of weight on drivers is somewhat a disputed point, the generally accepted proportion being four times the maximum drawbar pull, that is, if the tractive power is 25,000 pounds, the weight on drivers should be at least 100,000 pounds. This is because it has been found that this ratio will hold an engine from slipping on a good dry rail. For poor or slipping rails sand is used unless the weight is sufficient, say six times the tractive power.

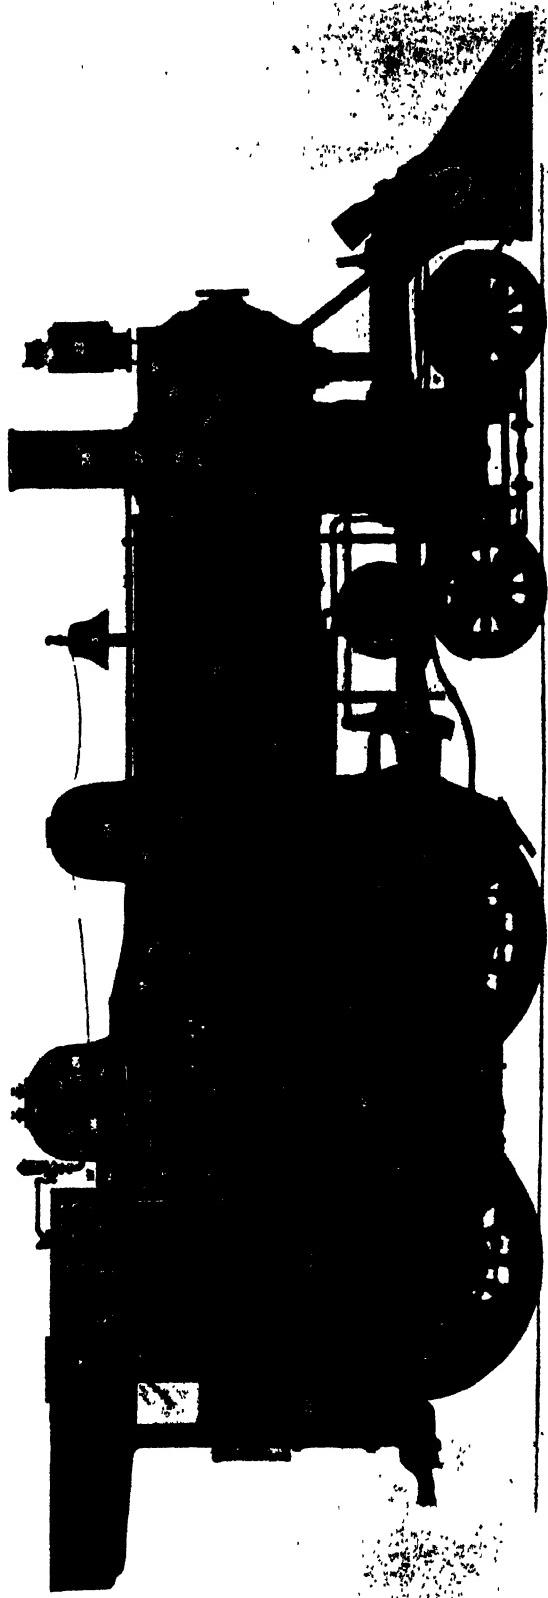

Although the number of driving wheels generally depends on the adhesion required, there are cases where light rails or poor roadbed prevent the necessary weight being put on the drivers needed for the work. In such cases more drivers are needed, more as carrying wheels than as drivers. In such cases, however, trailing or carrying wheels are used under the firebox. This is done on the Atlantic type of engine as well as on all single driver engines. The question of trucks under the front end seem to have been settled something as follows: Passenger engines on account of high speed, have a full truck to aid in rounding curves at speed. Freight or slow moving engines have a pony or half truck as in the mogul and consolidation engines. This gives the desired guiding of front end of engines and at the same time leaves nearly all the weight on drivers where it can do good work. In European countries freight or "goods" engines rarely have any trucks, all the weight being on the drivers, where it is effective for adhesion. This is possible on account of the roads being comparatively straight, but they would not do on our sharp curves on account of liability to derailment and wear of track.

Locomotive Types.—Classification was formerly accomplished by name only and as these varied somewhat in different parts of the country, the system caused some confusion. F. M. Whyte of the New York Central & Hudson River Railroad has devised a classification by numbers which is very simple, and which is being generally adopted. It consists of three parts to designate leading trucks, drivers and trailing trucks, each wheel counting one, thus 0-4-0

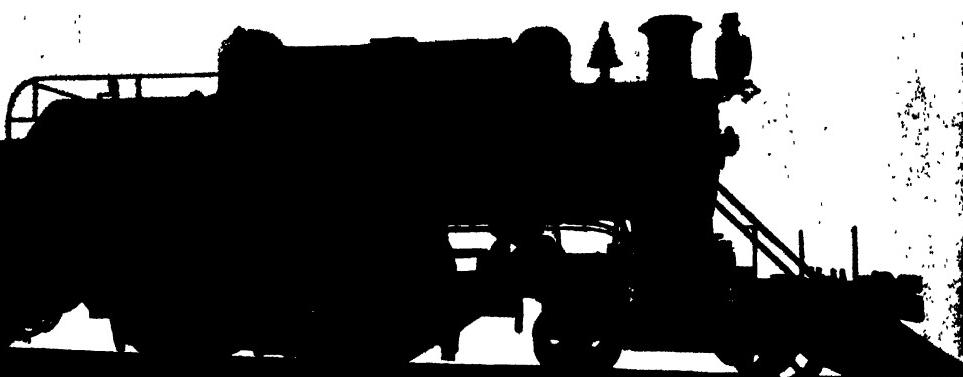

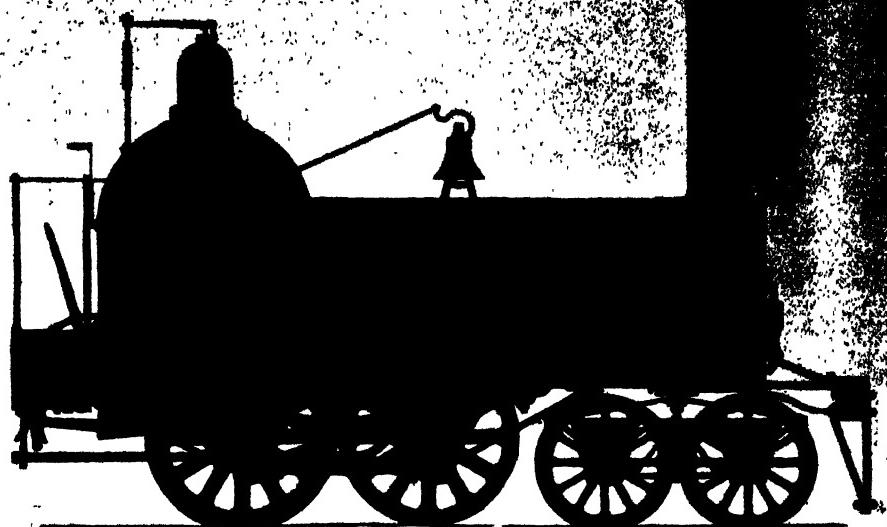

NAMES OF 240 PARTS OF A MODERN LOCOMOTIVE.

FRED H. COLVIN, M. E.,

Author, 'American Compound Locomotives.'
Locomotive Engine, The. In the course of three quarters of a century, a vast wilderness on the American continent has been changed from gloomy untrdden forests, dismal swamps and pathless prairies into the abode of a high civilization. Prosperous states teeming with populous towns, fertile farms, blooming gardens and comfortable homes have arisen from regions where savage men and wild animals united to maintain sterile desolation. The most potent factor in this beneficent change has been the operation of railroads by the locomotive engine.

Importance of Easy Means of Intercommuni-

cation.—Easy means of intercommunication have been properly encouraged by all nations and races that ever have made material progress in the arts of civilization. Lord Bacon says: "There are three things that make a nation great and prosperous—a fertile soil, busy workshops and easy conveyance of men and animals from place to place." That opinion was founded upon an intimate knowledge of the world's history; knowledge of the forces, the institutions and the conveniences that contributed to make nations great.

When the idea of applying the potential power of heat through steam to lighten the drudgery of mankind was little more than a philosopher's dream, when a practical steam engine was only a hope, its most useful field was by most far-seeing men considered to be in carrying heavy burdens and in bringing distant places into closer communication. The need of improved methods of transportation, which so long oppressed the human race, did not, however, produce the steam engine. Grim necessity brought it forth when great properties were falling into ruin, because sufficient animal power could not be concentrated to perform stupendous efforts in limited space. The steam engine was invented when horses could not do the work of pumping water out of valuable mines 500 feet deep. It was a foregone conclusion that the steam engine would be applied to locomotive purposes as soon as increasing business rendered animals unequal to the task of supplying necessary motive power on roads and on water ways. See RAILWAY TRANSPORTATION.

Slow Evolution of the Steam Engine.—After a practical steam engine was put to work on the simple operation of driving a pump, it took half a century of invention to develop it into a motor suitable for driving manufacturing machinery; another half century passed before inventors seriously began the attempt of building a steam engine that could be used to propel a vehicle on land. Far-seeing, progressive men who kept themselves informed on leading inventive achievements were convinced long before steam was applied to land transportation that peripatetic steam engines would be forthcoming when sufficiently urgent necessity would arrive.

When the 19th century opened, Great Britain, more than any other country, needed the use of the steam engine for help in land transportation. Tedious delay occurred before the mill driving engine was applied to vehicles, the principal obstacle being the weight of the ponderous slow moving condensing steam engine which James Watt (q.v.) developed and made popular. A new type was required which in due time was invented by Oliver Evans (q.v.), an American, and utilized by various British engineers. Evans had struggled to interest his own countrymen in his high pressure steam engine but they failed to recognize its merit and refused to aid the inventor. He sent drawings to Europe, hoping that he would be more fortunate with European capitalists. His designs fell into hands that returned no recompense or acknowledgment, but they were used to guide others in building engines that were used for land propulsion.

First Attempts to Produce a Steam Locomotive.—Early in the eighteenth century a variety

LOCOMOTIVE ENGINE

of attempts were made in England to produce a steam locomotive. Richard Trevithick (q.v.), a Cornish mining engineer, built several steam carriages for common roads and one engine to run on rails, but they were all failures although they possessed the elements that would have produced a successful locomotive in the hands of a persistent inventor. The first man to build a locomotive to run on rails and haul cars regularly was William Hedley, chief engineer of Wylam colliery on the River Tyne, near Newcastle, England. His first engine was not a success but his experience with its shortcomings enabled Hedley to build a second locomotive which worked fairly well, and is now to be seen in the South Kensington Museum, London, bearing the name of "Puffing Billy."

This engine (figure 1), which was built in 1813, had a return flue boiler, had upright cylinders and was a sort of grasshopper type of locomotive, which under a variety of modifications

gine, the front pair being the drivers, to which power was transmitted from two outside cylinders placed diagonally across the boiler pointing backwards. The first improvement made was to drop the cylinders to nearly a horizontal position which was followed by the cylinder being placed in the smoke box transmitting the power through a cranked driving axle. Most of the locomotive builders in Great Britain readily recognized the merits of the simple form of engine introduced by the Stephensons and the proceeded to develop the motor on similar lines.

Stephenson's Rocket.—There was no original feature about the Rocket, all the elements having been previously employed by other engineers, but the combination was the work of a master mind and gave to George Stephenson (q.v.) the reputation of being the inventor of the locomotive which is more than his due. When the locomotive is closely analyzed, we find that no proof exists of George Stephenson having

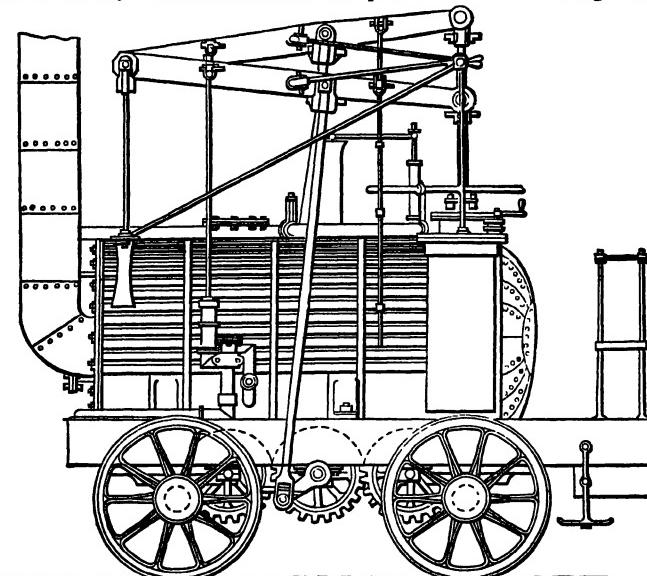

FIG. 1.

became the fashion and held the field up to 1829, when the directors of the Liverpool and Manchester Railway offered a prize for a locomotive that would fulfill certain practical requirements. A variety of locomotives were entered for competition and the prize was awarded to the "Rocket," made by George Stephenson & Son. This engine gave a new type of locomotive to the world which by mere increase of size is the locomotive of the 20th century.

Essential Elements of a Locomotive.—The elements combined to make a locomotive engine successful are a boiler that will generate steam rapidly and simple mechanism that will transmit the power directly to the driving wheels. The Rocket had a multitubular boiler, combustion being stimulated by exhaust steam passing through the smoke stack; and the cylinders transmitted the power to the driving wheels without the intervention of any useless beams or rods and the mechanism could be easily handled by one man.

The Rocket (figure 2) was a four wheel en-

gine, the front pair being the drivers, to which power was transmitted from two outside cylinders placed diagonally across the boiler pointing backwards. The first improvement made was to drop the cylinders to nearly a horizontal position which was followed by the cylinder being placed in the smoke box transmitting the power through a cranked driving axle. Most of the locomotive builders in Great Britain readily recognized the merits of the simple form of engine introduced by the Stephensons and the proceeded to develop the motor on similar lines. invented anything which became a permanent attachment. The tubular boiler had been applied to a boiler by Marc Seguin, a French railway master mechanic, several years before the Rocket was built, they were used in the United States in marine boilers before Stephenson's time, and the steam jet in the chimney had been used by Trevithick, Hedley, and others. But if Stephenson was deficient in inventive attributes he had the faculty of knowing a good thing when he saw it. He was one of the first men in Great Britain to realize that there was a great future for the steam engine as motive power for land transportation and he persisted in promoting the interests of the locomotive when it had few influential friends. Stephenson was a good representative of the best type of Englishmen. Opinionated and ever pushing his opinions with bulldog tenacity, he made weaker minds yield before his views on railways and locomotives. This was his hobby and he rode it so furiously that the British world was drawn along often against its will. By his dominant will, persist-

LOCOMOTIVE ENGINE

ent determination and forcible arguments, he prevailed on British capitalists to construct an expensive railway for general transportation and induced them to try locomotives when all the scientific world insisted that locomotives were impracticable. He gave his country the glory of originating steam operated railways at the moment when America was almost ready to grasp the prize of honor.

Within a year after the Liverpool and Manchester Railway was opened, a host of other railway enterprises were in progress. The first locomotive almost universally used at that time was carried on four wheels, one pair of small carrying wheels close to the smoke box and one pair of driving wheels in front of the fire box. The boiler was about nine feet long and included an internal fire box about three feet long. The furnace in the Hedley and other early locomotives was located in the internal flue, which in some cases provided the whole of the heating surface; in other cases an addition of a return flue was made. When the Rocket was designed it was determined to employ small tubes to convey the heat of combustion to the water in

wheels in front, a pair of large driving wheels in the middle and a pair of carrying wheels behind. It made a conveniently simple arrangement for light trains. When the single pair of driving wheels were found insufficient to provide the necessary adhesion, coupled driving wheels were introduced. For freight service European locomotive designers at an early day introduced the use of three pairs of wheels coupled with-

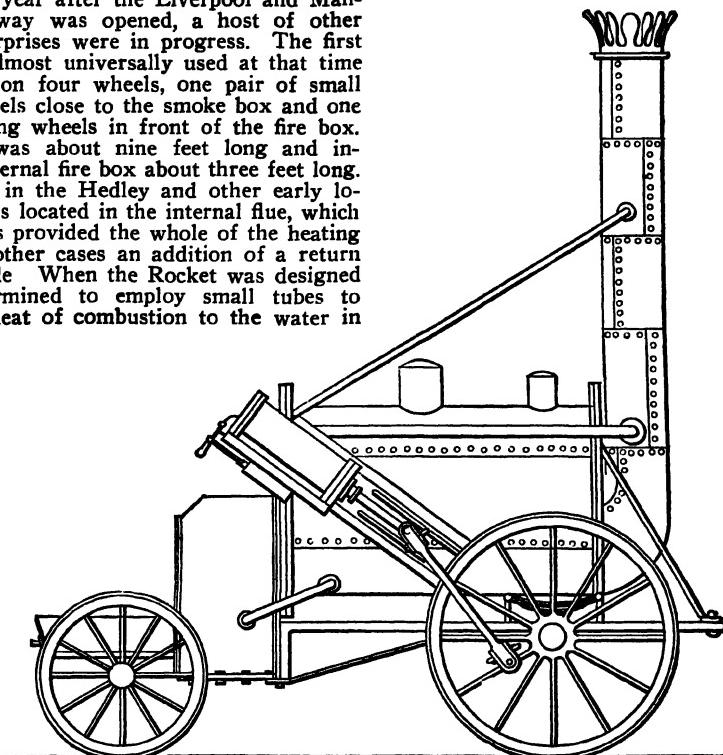

FIG. 2.

the boiler, a change which involved the use of a fire box as a furnace. That was made of rectangular section with flat walls which had to be strongly stayed to the outside shell, a water space being provided between the two surfaces. A smoke box with length about one quarter the diameter of the boiler was provided for the passage of the fire gases on their passage to the chimney. In the smoke box was located the opening of the steam exhaust pipe pointing straight through the center of the chimney and acting as a draft inducer. This combination of a multitubular boiler, a fire box surrounded by water and an exhaust steam jet located in the smoke box form the combined elements which make a high speed locomotive a possibility. They were first used together in the Rocket.

Development of the Locomotive in Europe.—The line of development exerted upon the locomotive was increasing the number of wheels and the proportions of boiler cylinders and running gear. In Europe the engine was at an early day provided with a pair of carrying wheels under the foot plate. The wheel arrangement then was one pair of small carrying

out any carrying wheels. That remained almost the universal practice until about 1900 when four pairs of driving wheels coupled began to find favor. On railways on the continent of Europe, British practice was closely imitated for years but in some cases very heavy multi-coupled wheel locomotives were used for freight service. In the British Isles inside cylinders were preferred with a plain slide valve operated by a link motion; on the Continent outside cylinders found most favor and articulated valve motion is more in favor than the link motion.

Genesis of Railroads in America.—The movement in favor of building railroads began in the United States about the same time as it began to influence public opinion in Great Britain. The 19th century had not advanced many years when people in the United States commenced to realize the urgent necessity for good arteries of intercommunication as a means of developing the extensive unsettled territory of the country. Statesmen were aware that the immense regions comprising the Roman Empire had been tied to the central government by a system of magnificent roads. There are numerous long reach-

LOCOMOTIVE ENGINE

ing navigable rivers and there are a great many inland lakes on the American continent, but geographically they are far apart and there is no means of reaching vast regions except by land transportation. A series of Appian Ways was the solution of land travel advocated by political leaders. To the ordinary thinker a system of macadam roads would have solved the difficulty; but such roads were not made to any great extent, for the cost of making them was beyond the means of a thinly populated country where material for road making was frequently very scarce. An agitation in favor of providing a system of canal for inland transportation led to the construction of a great many artificial water ways (see CANALS), but they proved to be a great disappointment. The world of the infant republic could not hold its pace to the speed of the slow moving canal boat, which was prostrated by frost a large part of the time. Some better means must be found to move the increasing volume of merchandise and grain and coal and ore to the centers of consumption. The pinch of necessity wonderfully quickens the inventive faculties. Long before a mile of railroad was built in the United States, the seers, the men of penetrating vision, were discussing

railroad construction was inaugurated in the United States. Crude forms of locomotives had been used in the north of England for about fifteen years but even the scientific world of Great Britain knew almost nothing about them. It is not then surprising that Americans as a rule knew very little about what foreigners had done when they began building railways and their first locomotives were purely of original design. Very little accurate information had reached America concerning what had been done abroad before our people proceeded earnestly with the building of railroads. Before the railroad era there was scarcely any means of circulating scientific information, and few Americans had any idea of how railroads and the motive power for operating the same ought to be built, but that was considered no obstacle; they proceeded vigorously to construct railroads, learning the business over many expensive mistakes. The nation has always been noted for self-reliance, and the pioneer railroad builders pushed along without hesitation, crossing the bridges of difficulty when they were reached. When a portion of the Baltimore and Ohio Railroad was ready for business in 1830, few people believed that locomotives could be built that could oper-

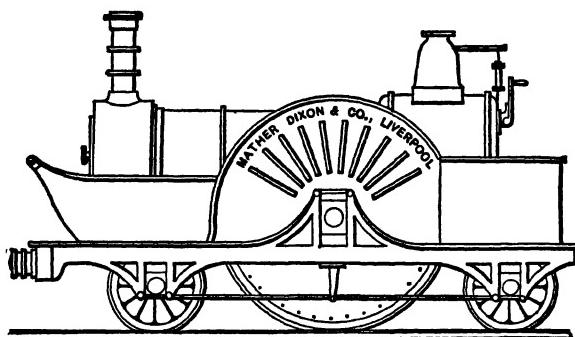

FIG. 3.

the possibilities of the steam engine as a means of accelerating land travel. The high pressure steam engine had been invented by Oliver Evans (q.v.), a native of Delaware, as an improvement of the Newcomen engine. Associated with the Evans engine were ideas of portability that were suppressed in the presence of Watts' ponderous slow-moving engines.

Colonel John Stevens (q.v.), a very influential American citizen, as early as 1812 advocated the use of railroads and in that year published a pamphlet on the superior advantage of Railways and Steam-carriage and Canal Navigation in which he outlined schemes of construction which were not greatly deviated from when actual railroad building commenced. The views of Colonel Stevens began gradually to have supporters and the sentiment in favor of railroad building spread slowly.

Baltimore and Ohio Railroad.—The first practical move of any importance was the building of the Baltimore and Ohio Railroad which was chartered in 1827 and partly opened in 1830. Other railroads were under construction at the same time and 1830 may be noted as the natal year of the American locomotive. Little was known anywhere about locomotives when

ate the road which was remarkably crooked. Popular belief was that hauling railroad cars would be a new line of enterprise for the mule that had supplied motive power to the canals. But Peter Cooper (q.v.), a merchant of Baltimore, considered that the use of steam was essential to make railroad operating a success and he had a small locomotive built to prove the faith that was in him. His engine, the "Tom Thumb," was little more than a model but it developed one and a half horse power and proved that a steam locomotive could be used in operating around very short curves.

Cooper's "Tom Thumb."—The Tom Thumb has an upright multitubular boiler but no claim for originality was advanced for it, as Nathan Read, of Warren, Mass., had patented such a boiler in 1791. The single cylinder was upright and transmitted power to the driving axle through a gear wheel. The engine performed the work for which it was built and for a time its form exercised considerable influence on the designing of American locomotives. Shortly after the experiments were made with Peter Cooper's model, the Baltimore and Ohio Railroad Company advertised, offering a premium of \$500 for a locomotive built in the United

LOCOMOTIVE ENGINE

States which would meet certain specified conditions. The offer brought to the company five locomotives all built at different places, all of original design and all of them practical engines. That which was selected was built by Phineas Davis, of York, Pa. It had upright boiler and cylinders, after Cooper's idea, and was the first in America of a class of engines called "grasshoppers" that were a familiar feature on the Baltimore and Ohio Railroad for many years. The upright boiler and cylinders did not appeal to the mechanical men of other railroads. Most of them had engines built with a horizontal boiler resting on an oblong frame which carried the cylinders and secured the running gear. Even the small engines resting on four wheels were found to act injuriously upon the slender track of the pioneer railroads and the first important improvement effected by American engineers was putting the weight upon three pairs of wheels, two pairs forming the leading truck. This was done in 1832 by John B. Jervis (q.v.), chief engineer of the Mohawk & Hudson Railroad. That leading truck soon came to be a regular feature of American locomotives.

Jervis Invents the Four Wheel Truck.—

engine, which had a pony truck in front consisting of a single pair of wheels and three pairs of driving wheels connected. This gave the means of using a greater proportion of the weight for adhesion than was practicable with a ten wheel engine of the same weight.

Working Out Details.—For many years American railway master mechanics worked on making a locomotive as simple as possible, and the working parts were so proportioned and arranged that the repair expenses would be as low as possible. Various forms of running gear and foundation supports were tried; wooden frames, combined wood and iron frames, outside and inside frames made of iron plate or of iron bars. The fittest to survive were inside iron bar frames which for one decade before the 20th century began were gradually giving way to cast steel. The boiler material for many years was iron with, in some instances, copper fire boxes and brass tubes. The fuel used for the first 40 years of the railroad era was almost exclusively wood, but that became so dear in some quarters that the burning of coal had to be introduced. When that was successfully accomplished it was found that copper fire boxes and brass tubes wore rapidly from the attrition of the hard par-

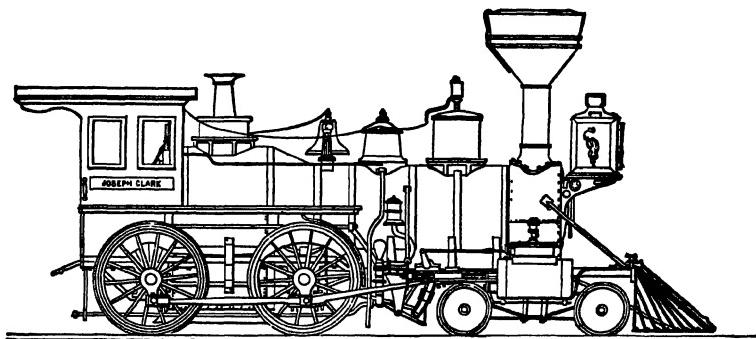

FIG. 4.

The course of evolution of the American locomotive turned upon methods of making the engines more powerful with due regard for the weakness of the rails the trains had to run upon. For about 20 years after the first locomotive was put to work in the United States, the design worked out by Jervis of a single pair of driving wheels and a four-wheel truck was the prevailing type. Then another pair of driving wheels was added, these being coupled to the main driving wheels, making what was long known as the American locomotive (figure 4). An important improvement effected upon this engine was placing equalizing beams between the driving wheels, which modified the shocks given by imperfect track.

The railroad companies having the haulage of coal, metals and other heavy freight began about 1850 to introduce locomotives of much greater power than the eight-wheel engine and those with six coupled wheels worked gradually into favor. Some companies used six-wheel connected engines without any carrying wheels; but the favorite heavy engine for many years was known as a ten wheeler, its arrangement being a four wheel truck and three pairs of driving wheels coupled. Then came the mogul

ticles of the coal. This led to the universal introduction of iron for fire boxes and tubes. The heat generated in a coal burning fire box is so intense that it was found to create blisters and flaws in the imperfectly welded iron. After much careful manipulation a mild form of steel was produced that proved a safe, strong and durable material for fire boxes. When this fact was satisfactorily demonstrated steel took the place of iron and it is still the only material used for locomotive fire boxes on the American continent. The successful use of steel fire boxes led to the same material being used for boiler shells. There again it proved itself superior to iron and all locomotive boilers are now made of mild steel.

The lines of progress then pursued by American railway mechanical engineers were: maintaining simplicity of parts while increasing the proportions for the purpose of making the locomotive sufficiently powerful to meet the requirements of fast and heavy trains. The fragile track over which the early locomotives were operated called for extraordinary care in reducing as far as possible the shocks resulting from the moving of the power-producing machinery, and of the running gear. Counterbalancing the driv-

LOCOMOTIVE ENGINE

ing wheels and reciprocating parts of the engine received the greatest possible attention, and equalizing beams were introduced at an early day to distribute evenly among the wheels and springs the concussions caused by low joints and other defects of the track. Steel wheel tires that are almost immune from breakage gradually took the place of cast iron and wrought iron, which were originally employed exclusively for tire-making. Experience and theory both having demonstrated that high boiler pressure was necessary to produce economical use of fuel, a high quality of steel was produced for the construction of boilers and furnaces, with the most gratifying results. Steel boiler tubes have taken the place of copper, brass, or iron, and failures from this troublesome part of a locomotive boiler have been reduced to the lowest limits. Not a small part of the increased efficiency of boilers is due to highly perfected appliances provided for feeding the water. Injectors that can be regulated to supply exactly the volume of feed water required have pushed out of service the erratic and unreliable force pump, a change which protracts the life of the boiler by obviating extremes of temperature.

Although it was of the utmost importance for the safety of the public, and of every one connected with the operating of the locomotive, that the boiler pressure should be maintained below a certain tension, serious defects were long common in the construction of safety valves, with the result that boiler explosions were painfully common. In fact, one of the pioneer railway companies advertised that it kept a car loaded with cotton bales next to the engine to prevent passengers from being injured when the boiler exploded. That source of danger has gradually been eliminated, and modern safety valves may be depended upon to prevent the steam pressure rising more than two or three pounds per square inch above the blowing-off point.

The efficiency of the engine has been decidedly improved by setting the cylinders horizontally, thereby providing for direct transmission of power in line with the axles.

In the pioneer days of locomotive building, very little attention was bestowed upon the lubrication of valves and cylinders, an intermittent charge of tallow being considered sufficient, a practice which led to serious loss of power through excessive friction. The attention of inventors was directed to this defect of the locomotive, and a long line of patented lubricators were produced. The latest appliances for lubricating valves and pistons are now so efficient that a constant supply of lubricant is assured.

For many years after locomotives came into use great efforts were made and much expense incurred in giving the engines an ornate appearance. That fashion was gradually abandoned, and severe simplicity of form and modest coloring is more consonant with the character of the modern locomotive.

Sixty-Miles-an-Hour Engines.—When the locomotive had been in use in this country about 20 years, there arose an agitation for engines that would maintain a speed of about 60 miles an hour. Under this demand a number of locomotives were built with a single pair of driving wheels, but the movement toward high speed was short lived. Most of these high speed

engines resembled the English engine, figure 3. The designers of such engines appeared to think that the size of cylinders and driving wheels formed the measure of the speed capacity of a locomotive, but dearly bought experience taught them that the real controlling element is the size of boiler, which, in the engines referred to, was very small. For many years the growth of the locomotive was restricted by the comparatively fragile iron rail. The iron rail wore so rapidly and laminated so badly under heavy or sharp wheel impact, that prudent railroad managers generally restrained other officials in their zeal to increase the hauling power, and therefore the weight, of their locomotives. Until steel rails were introduced the subject of wear of rails was one of extraordinary solicitude to railroad managers.

Steel Rails.—In 1870 steel rails were beginning to be appreciated for their extraordinary wearing qualities. That time may be regarded as the beginning of the movement toward making the locomotive as powerful as it is possible to make a motor which has to run on a rail gauge of 56½ inches and pass under bridges and tunnels about 15 feet high. In 1870 the vast majority of locomotives in the United States were of the eight-wheel or American type, with cylinders 16 x 24 inches, driving wheels 60 inches in diameter, heating surface 900 square feet, grate area 12 square feet, total weight 50,000 pounds. Such an engine was used for all species of service, and was justly considered the best all-round locomotive that had even been employed. The wear-resisting steel rail has permitted locomotive builders to develop the eight-wheel engine until it has become common to carry 20,000 pounds on each driving-wheel, and as much as 25,000 pounds per wheel has been tried. That was beyond the limit of cool journal impact and led to the introduction of more driving-wheels, or a pair of carrying wheels under the foot plate in the highly popular locomotive known as the "Atlantic" or 4-4-2 type.

Increasing the Boiler Capacity.—The development of the boiler to supply steam to cylinders as large as 23 x 32 inches was the result of very skillful and ingenious labor performed by the most accomplished locomotive designers in the country. To produce a boiler of liberal steam-generating capacity it was necessary to increase the grate area. With the eight-wheel engine, which became the object of development, the fire-box was between the frames and the forward and back driving axles. Under these conditions the width could not be more than 34½ inches and the length 72 inches, so that little more than 17 square feet of grate area could be secured. When attempts were made to force these small fire-boxes to their utmost, it became a common practice to urge the fire with such intensity that from 100 to 200 pounds of coal per square foot of grate area would frequently be burned per hour. This was done with great waste of fuel and with destructive effects upon the fire-box. The necessity for an abnormally large grate to burn anthracite coal induced James Millholland, superintendent of motive power of the Philadelphia & Reading Railroad, in 1857, to place the grate above the frames, which gave a material increase of grate surface. Zerah Colburn, in 1854, designed some engines for a road which is now the Delaware, Lackawanna & Western Railroad, with fire-box 7

LOCOMOTIVE ENGINE

feet 6 inches wide and 6 feet long, providing 45 square feet of grate area. These fire-boxes were entirely behind the driving wheels, and the engines were not adapted to anything except very slow service. Millholland modified the Colburn design in a boiler patented in 1862. This boiler had an overhung fire-box, a combustion chamber, and other features that enabled it to burn anthracite coal successfully. In 1877 John E. Wootten, general manager of the Philadelphia & Reading, patented a boiler with a fire-box extending over the driving wheels, which was practically the first of a type now largely used. The circumstances which influenced the designing of boilers with very large grate surface did not move the railroad men in charge of bituminous coal-burning engines until after the advent of steel rails. The rapid increase in the capacity of locomotives that followed the improvement in the track compelled the locomotive designers to devote attention to the increasing of the grate area. This induced them to adopt Millholland's plan of putting the grates above the frames, and to making them as long as possible consistent with the ability of a fireman to cover the front part with fuel. The limit of burning a moderate amount of coal per square foot of grate was again soon reached, because demands for more powerful locomotives continued, and the physical limit imposed by bridges and permanent structures still left some possibility of increasing the size of the engines. The next step to provide a fire-box with increased grate area was made by the Baldwin Locomotive Works in 1895 by the introduction of the "Atlantic" type, 4-4-2, designed by S. M. Vauclain. In that form the fire-box may be made as wide as a sleeping-car, which enables the designer to use a grate large enough for any locomotive that can be built to meet the restrictions of track and bridges, and may be regarded as final under existing conditions.

Introduction of Compound Locomotives.—American railroad managers have never been exacting in putting restrictions upon the amount of fuel used by locomotives, regularity of service and freedom from break-downs being considered of most importance. But so much had been said and written about the reduction of fuel expense that might result from the introduction of compound locomotives (see LOCOMOTIVES, COMPOUND), that various railroad companies began about 1890 to purchase engines of that character. In this year of grace 1904 there are probably 10,000 compound locomotives in use in North America. There are a variety of types, two-cylinder compounds with high pressure cylinder on one side and low pressure cylinder on the other. The four-cylinder Vauclain compound is more numerous than all the others combined. It has two cylinders on each side transmitting the power through a single cross-head. There are a few tandem compounds in use that have two cylinders in line on each side; and there are a few four-cylinder compounds with two of the cylinders outside on the frames and two cylinders below the smoke-box, the latter transmitting the power through cranked axles. This type of locomotive promises to become the most efficient type for heavy passenger train service. The compound locomotive has not achieved real popularity with railroad men, and, so far, the purpose of their introduction has not been fulfilled. They have not performed

the work of hauling trains at less expense than the simple engine.

About 20 per cent of the fuel placed upon the tenders of locomotives is used for other purposes than that of hauling trains. Part of that is used for raising steam, part for keeping the boiler hot when the engine is not working, and part is wasted through the safety valves and other sources of leakage. This leaves only 80 per cent of the fuel used as a basis for saving by compounding or other improved methods of using steam. The weight of evidence goes to show that the saving effected by compounding is about 8 per cent. If a compound locomotive is not capable of running as many miles per year as a simple engine, a charge of inefficiency will stand against it. Railroad managers complain that the compound loses mileage as compared with a simple engine, and that it is more expensive to keep in working order, so that the saving of fuel is generally overbalanced by other expenses.

Efficiency of Fuel.—An ordinary locomotive develops one horse-power for from 12 to 15 minutes per pound of coal burned in the fire-box equivalent to four or five pounds of coal per horse-power per hour. Engines worked under particularly favorable circumstances may double the duty per pound of coal consumed, while others again will not produce one horse-power short of six or seven pounds of coal per hour. Under favorable conditions a locomotive compares fairly well with a good stationary engine, under the unfavorable conditions of being forced so that the steam passes out of the cylinders at nearly steam-chest pressure, no measure of economy ought to be expected. Predictions are rife that the days of the steam locomotive are numbered, and that electric power generated cheaply in huge central stations will in the near future move the passenger and freight trains now drawn by toiling locomotives. This prophecy may be true, but when the last steam locomotive is consigned to the scrap heap or to the Smithsonian Institution, it will be well to credit it with having performed noble service to the human race.

Reduced Cost of Transportation.—As motive power for the transportation of freight and passengers, the locomotive has steadily increased in efficiency ever since Cooper's "Tom Thumb" wound around the sharp curves of the Maryland hills. At the time that feat was performed the cost of moving flour from Columbia to Philadelphia over a State-made turnpike was 13.51 cents per ton per mile. Transportation was so expensive in regions remote from water carriage as to be prohibitive except for articles of special value. In 1823 John Stevens, of Hoboken, obtained from the legislature of Pennsylvania a charter to build a railroad from Philadelphia to Columbia, in which he was authorized to charge 7 cents per ton per mile. In 1870 the charge for a bushel of wheat per rail from Chicago to New York was 26.11 cents. Under the influence of steel rails and heavy locomotives the rate per bushel of wheat from Chicago to New York had dropped in 1899 to 11.6 cents. An item in 'Railway and Locomotive Engineering' says that when the volume of freight was large enough James J. Hill had carried 10 barrels of flour 10 miles for 1 cent. A barrel of flour weighs 196 pounds, so Mr. Hill has carried 1,960 pounds 10 miles for 1

LOCOMOTIVE AND ENGINE INDUSTRY

cent, presumably at a profit. The steady decrease in freight rates will be understood by an examination of the annexed table. The distance from Chicago to New York is about 1,000 miles. The figures in the table apply to any territory for the whole or a part of the distance hauled.

RATES IN CENTS PER BUSHEL OF WHEAT AND CORN FROM CHICAGO TO NEW YORK.

YEAR	WHEAT		CORN	
	By rail Cents	By rail and water Cents	By rail Cents	By water Cents
1870	26 11	19.58	24.37	19 32
1880	19 8	15.8	17.48	14.43
1890	14 3	8 52	11 36	7 32
1900	10 8	10 1
1904	11 4	10 6

Influence of Steel Rails and Huge Locomotives.—The use of steel rails and huge locomotives has exerted tremendously far-reaching effects and has created social revolutions in certain parts of the world. They brought the cereals of regions west of the Missouri River and of the remote Northwest into competition with the grain-raising districts of the Eastern States and with those of Europe, Africa, and Asia. It threw many farms in New England and along the Atlantic seaboard out of cultivation, and it caused a semi-revolution in farming business in the British Isles, strongly affecting the condition and fortunes of millions of people. Irish peasants used to go in thousands to England and Scotland to work on the harvesting of the grain crops, thereby earning enough money to pay the rent of their small holdings. Steel rails and consolidation locomotives stopped the cultivation of so many grain fields in the British Isles that the help of the Irish worker was no longer needed. The suffering and discontent arising from the changed conditions led to the vigorous agitation for home rule in Ireland; and in the year 1904 an agitation exists for a duty on grain entering Great Britain, for the protection of British farmers.

While inflicting injury and suffering upon the few, progress as represented by Bessemer's great invention and by the enterprise of American railway master mechanics has exercised a beneficent influence upon the many, and the world at large has been a great gainer from the skill and the enterprise of the inventor of a marvelous system of steel-making, of the American mechanic, of the engineer, of the railroad constructor, and of the railroad manager. They have together built a monument to progress which will always be regarded by a grateful people as one of the highest achievements the world has ever witnessed. ANGUS SINCLAIR,
Editor 'Railway and Locomotive Engineering.'

Locomotive and Engine Industry. It is not difficult to trace the inception and progress of locomotive engineering in the United States. Although other lines of rails had previously been laid for special purposes, the Baltimore and Ohio and the South Carolina railroads — both begun in 1828 — were the first American railways constructed to carry passengers and freight. Upon the former was run the first American-built locomotive, that of Peter Cooper, constructed in 1829, a mere working model, not intended for permanent service, but to demonstrate the practicability of operating the line

by locomotive power. It did this successfully, and led to the completion of the road, which otherwise might have been abandoned. This little machine, with a single cylinder three and a half inches in diameter, a boiler no larger than that of an ordinary kitchen-range, and tubes improvised from gun barrels, on its trial run attained a speed of 18 miles an hour, and hauled 40 passengers besides the driver, who was Peter Cooper himself. The first locomotive for real service used in the United States was the Stourbridge Lion, built at Stourbridge, England, and imported by Horatio Allen, in 1829, for the Delaware & Hudson Canal Company. In 1830, the first locomotive constructed in the United States for actual work, the Best Friend, was built by the West Point Foundry, for the South Carolina Railroad. In 1831 Matthias W. Baldwin, a manufacturer of bookbinders' tools, of Philadelphia, was engaged by the proprietors of Peale's Museum, of Philadelphia, to construct a model locomotive to operate on a circular track, to satisfy the public curiosity growing out of the Rainhill contest, in England, which had resulted in a victory for Robert Stephenson's Rocket, and which was then attracting widespread attention. In September 1832, there were built at York, Pa., by Davis & Gartner, three locomotives of the "grasshopper" pattern, for the Baltimore and Ohio Railroad, from designs of Phineas Davis and Ross Winans. Some of these locomotives continued in service about 60 years, and were in use at Mount Clare, in Baltimore. The success of the Peale Museum model was such that Mr. Baldwin was employed by the Philadelphia, Germantown and Norristown Railroad Company, in 1831, to construct a locomotive for their line. This locomotive, Old Ironsides, was completed in November 1832. It was a four-wheel engine, similar to the English design of the day, and weighed in running order over five tons. The rear, or driving wheels, were 54 inches in diameter, placed on a crank axle. The cylinders were $9\frac{1}{2}$ inches in diameter, by 18 inches stroke, and were attached horizontally to the smoke-box; the frame was of wood; the wheels had heavy cast-iron hubs, wooden spokes and rims, and wrought-iron tires; there was no cab; and the tender was four-wheeled, with wooden sides and back for holding the wood used for fuel, and an iron box for water-tank. This locomotive attained a speed of 30 miles an hour, with its train attached, and upon a special occasion it is said to have attained a speed of 60 miles per hour. Locomotive engine building may be said to have become fairly established by 1834; but in those early days, when there was no practice to guide, skilled workmen were few, and few shop facilities existed, the difficulties surrounding the locomotive builder were extraordinary, and only the most indomitable perseverance attained success. The American pioneers of railway mechanics were Cooper, Allen, Baldwin, Rogers, Norris, Winans, Campbell, and their co-workers, and later William Mason, Cooke, McQueen, Millholland, and Hudson.

The early American locomotives were similar in all essential features to the English engines of the day, being constructed from published descriptions or from actual observation of them. The importation of English locomotives did not long continue, for the early American builders soon made radical departures from

LOCOMOTIVE AND ENGINE INDUSTRY

the English types. The steps by which these differences were reached were the substitution of a four-wheel swiveling truck or bogie for the pair of fixed carrying-wheels (1832); the use of the cross-head pump for supplying feed-water to the boiler (1833); the use of the half-crank driving-axle in place of the crank-axle (1834); the introduction of outside connections to the driving-wheels (1835); the coupling of two pairs of driving-wheels, patented by H. R. Campbell (1836); the use of counterbalance weights for the revolving and reciprocating parts (1837); of lap-welded wrought-iron boiler tubes (1838); of bar-frames of forged iron with forged pedestals (1840); of wooden cabs with glass windows, which originated about 1840 in New England, where protection for the engine-men was necessary on account of the severity of the winters; the introduction of Baldwin's flexible-beam truck (1842); the connection of equalizing beams with the driving-wheels, invented by Eastwick and Harrison (1845); the use of the "ten-wheel" locomotive, with six coupled wheels and a leading four-wheeled truck (1846); and the use of the Mogul locomotive with six coupled wheels and a leading two-wheel truck (1861), and of the Consolidation type, with eight coupled wheels and a leading two-wheel truck, designed by Alexander Mitchell of the Lehigh Valley Railroad, and built at the Baldwin Locomotive Works in 1866. Other features of the American locomotive appear to the foreigner to be peculiar, such as the pilot or "cowcatcher," the bell, the boiler covering of planished or Russia iron, the large headlight, and the directness and visibility of the pipes and other appurtenances. The aim of American locomotive designers has been to produce a machine having the maximum flexibility of wheel-base to enable it to pass sharp curvature and adapt itself to the unevenness of track subject to the action of severe frosts; and to provide for repairs by making every part accessible and removable without affecting other parts. Prior to the Centennial Exhibition of 1876, it was frequently customary to use gaudy painting and forms of unessential parts supposed to be ornamental; but during the period of business depression and retrenchment of 1876 the railroads learned to dispense with this source of expense. This cause, together with the improvement in the public taste which was coincident with, or the result of the Centennial, led to the abandonment of fancy painting and molded or beaded ornamentation, and the substitution of smooth, appropriate forms, painted in plain dark colors, with little or no striping. In the early 50's the "American" type, with four coupled wheels and four-wheeled truck, patented by Campbell in 1836, had become the most generally adopted class of locomotive, and was for many years thereafter used for general service—passenger, freight, and switching. The growing traffic of the railways, however, created the need for more powerful locomotives constructed especially for freight service, as well as for engines better adapted for switching than old road locomotives, so that, in the '60's, the Mogul and ten-wheel types were widely adopted, and between 1870 and 1880 the Consolidation type became the recognized standard for the heaviest freight service. Prior to 1880, the general use of iron tires and iron rails of light section, usually not exceeding 50 to 60

pounds per yard, limited the weight per axle to about 12 tons as a maximum; but about that year the general substitution of steel tires and the growing use of steel and the introduction of the heavier rails possible in steel, together with an awakening to the advantages of larger heating surfaces in locomotive boilers, led to the acceptance of greatly increased weights. This tendency has since grown constantly. The use of heavier, more powerful locomotives made practicable economies in transportation by the use of cars of larger carrying capacity, which in turn required still heavier locomotives to move them. The limit seems to have been reached with the present car loads of 50 tons, which are about as large as will serve the convenience of shippers. The heaviest locomotives of 1901 had as much as 30 tons' weight per axle.

Among the locomotive-building establishments which have contributed a share to the motive-power of the past, and have either disappeared altogether or have discontinued the manufacture of locomotives for other lines of business in which competition is less intense, may be mentioned the works of Norris Brothers, of Philadelphia, which in early days were active competitors of Baldwin and Rogers, but which, after many vicissitudes, went out of existence in 1865. These works in part are now included in the plant of the Baldwin Locomotive Works. Baltimore had the works of Ross Winans and the Denmeads. Boston has had the works of Seth Wilmarth, the Globe Works of John Souther, and the works of McKay & Aldus at East Boston, and the Hinckley Locomotive & Machine Works, one of the oldest, occupied an honorable position in the business until about 15 years ago. New England has been an active locomotive-building section; in addition to the works mentioned may be noted those of Ballard Vail, Andover, near Boston, Mass.; Corliss & Nightingale, Providence, Geo. H. Corliss, the great engine-builder, proving less successful in the manufacture of locomotives; A. Latham & Company, White River Junction; the Amoskeag Locomotive Works at Manchester, N. H.; the Locks and Canals Works at Lowell, Mass.; a works at Lawrence; and later the Taunton Locomotive Works, the Mason Machine Works, and the Portland Locomotive and Car Company, three concerns which later left the business. New Jersey also has been a prolific field of locomotive-manufacture: an offshoot from the Rogers Works was that of William Swinburne, of Paterson, subsequently called the New Jersey Locomotive Works, and finally the Grant Locomotive Works. Finding their shops antiquated and their appliances inadequate to modern requirements, the Grant Works ceased business at Paterson in 1885, and reorganized with new capital and new shops at Chicago. This plant succumbed to the financial storm of 1893, and was sold to the Siemens & Halske Electric Company, which for a time operated it under its own name for the manufacture of electrical equipment and locomotives, but this proved to be unprofitable, and the works are now abandoned. For many years Breese, Kneeland & Company operated the Jersey City Locomotive Works at Jersey City, and Van Cleave, McKean & Dripps had shops at Trenton. Eastwick & Harrison were builders of locomotives at Newcastle, Del., but, failing in 1840, were succeeded by the Newcastle

LOCOMOTIVE AND ENGINE INDUSTRY

Manufacturing Company, who subsequently gained fame and wealth in railway operations in Russia. In the West were the Cuyahoga Works of Cleveland, those of Scovill at Chicago, Booth & Company at San Francisco, and others at Detroit and Milwaukee. Later the Rome Locomotive Works, at Rome, N. Y., entered the field, but had only a few years of disastrous existence, which ended in 1891. The list might perhaps be extended further, but it is a more agreeable task to record the works which were in business in 1901 to 1903.

The Baldwin Locomotive Works of Philadelphia were established in 1831 by Matthias W. Baldwin, as has before been mentioned. The annual capacity is more than 1,200 locomotives. The works occupy 16 acres in the centre of the city. A number of the buildings of later construction are from four to six stories high and of the most substantial character. Employment is given to upward of 10,000 men. The total production of these works from their establishment to 1901 was nearly 20,000 locomotives.

The Rogers Locomotive Works, of Paterson, N. J., were founded in 1836 by the firm of Rogers, Ketchum & Grosvenor. The mechanical head and dominating spirit was Thomas Rogers. Upon his death in 1856 the business was incorporated under the title of The Rogers Locomotive and Machine Works, of which Jacob S. Rogers was president. Owing to J. S. Rogers' increasing age, the company was reorganized in 1892 under its present title of The Rogers Locomotive Company. These works give employment to about 1,400 men, and have an annual capacity of 250 locomotives.

The period of business prosperity which followed the war with Spain in 1898 was marked by the consolidation of the competing members of many industries into large corporations or so-called "trusts." This movement extended to the locomotive industry and the eight works next mentioned were in July 1901 purchased and united into one organization known as The American Locomotive Company. Its officers are S. R. Callaway, president; Albert J. Pitkin, first vice-president; R. J. Gross, second vice-president; Leigh Best, secretary, and James E. Sague, mechanical engineer. This company has a capital of \$50,000,000, half of which is common stock and half is cumulative, 7 per cent preferred stock. The works acquired by the company, with the approximate capacity of each, are as follows:

	Locomotives per annum
Schenectady Works, Schenectady, N. Y.....	450
Brooks Works, Dunkirk, N. Y.....	450
Pittsburg Works, Pittsburg, Pa.....	200
Rhode Island Works, Providence, R. I.....	150
Richmond Works, Richmond, Va.....	150
Cooke Works, Paterson, N. J.....	125
Manchester Works, Manchester, N. H.....	100
Dickson Works, Scranton, Pa.....	85
Approximate total capacity.....	1,710

Following is a brief sketch of the history of each of these works: The Schenectady Locomotive Works established by Norris Brothers in 1848, passed into the sole control of John Ellis in 1863, who was succeeded by his sons, John C. Ellis, Charles G. Ellis, Edward Ellis, and William D. Ellis, in succession.

The Cooke Locomotive and Machine Company of Paterson, N. J., began the manufac-

ture of locomotives in 1852. The works were established about 1800, and for 50 years were engaged in the manufacture of cotton and other machinery. The original shops in Paterson have recently been abandoned to other uses, and new and completely modern shops have been built.

The Pittsburg Locomotive Works, organized in August 1865, were completed so far as to construct their first locomotive in the latter part of 1866. The works were originally designed for a capacity of 30 locomotives a year, but by the construction of new fire-proof buildings, and the addition of new and improved machinery, the capacity has been gradually increased. The works occupy nearly 12 acres of ground, and their equipment includes the most improved hydraulic, pneumatic, and electric appliances for fashioning the work and handling materials. There is also a completely appointed laboratory for chemical and physical tests of materials.

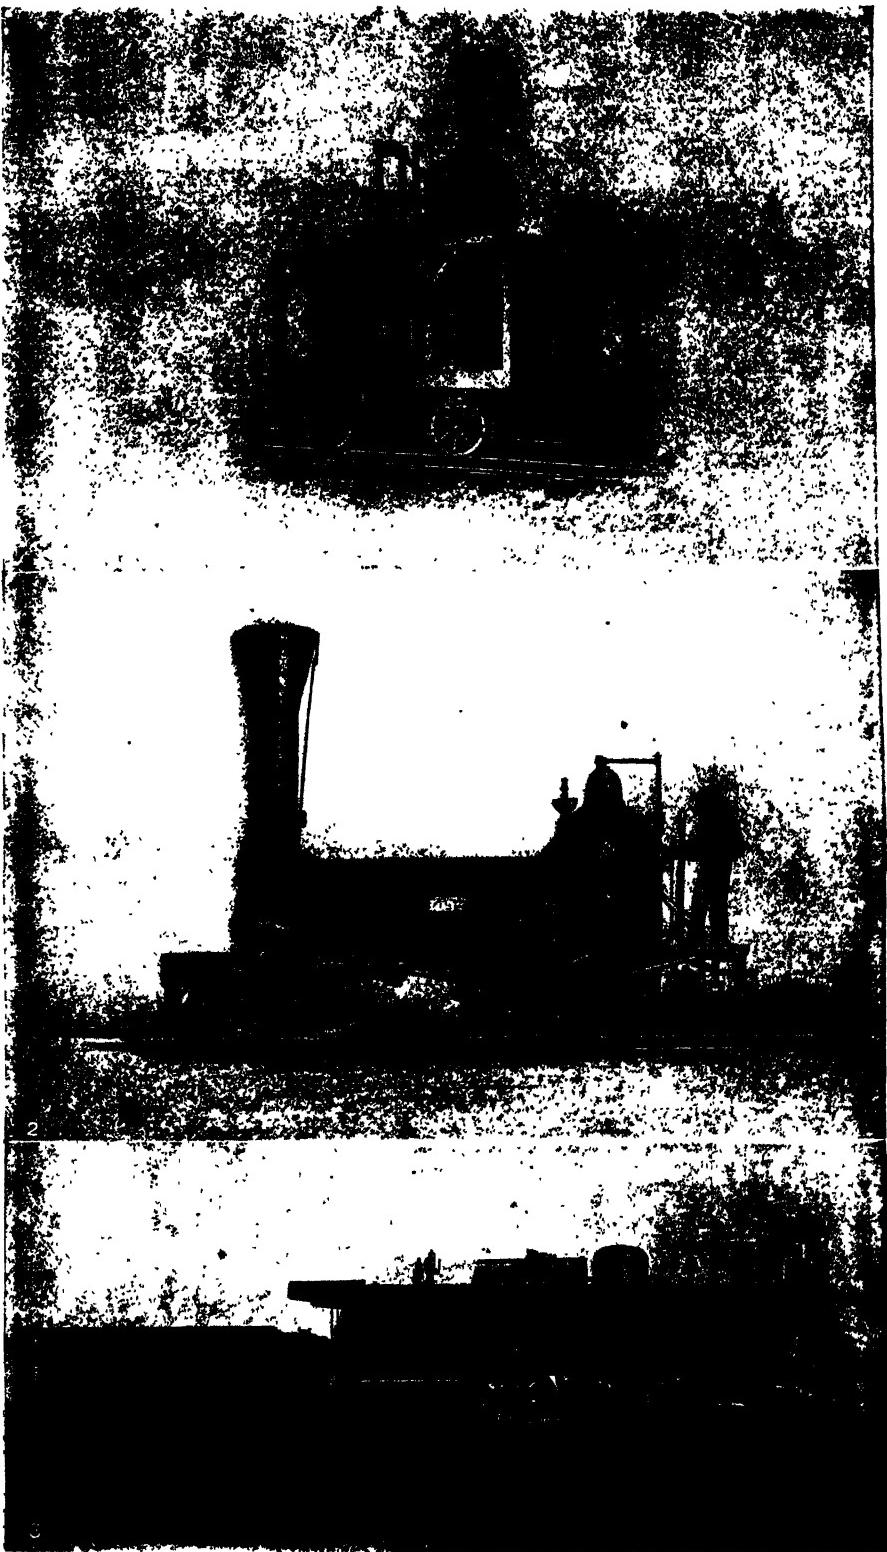

The Rhode Island Locomotive Works of Providence were likewise established in 1865. These works have occupied an important position in the field of locomotive manufacture.

The Brooks Locomotive Works of Dunkirk, N. Y., were originally constructed as the locomotive building and repair shops of the Erie Railway. In 1869, Jay Gould, then president of the Erie Railway, having completed extensive shops at a more central location on the line of that road, ordered the Dunkirk shops to be permanently closed, and the machinery removed to other locations. Horatio G. Brooks, at that time superintendent of motive power and machinery of the Erie Railway, whose home was at Dunkirk, and whose interests were identified with the welfare of that place, made a proposition to Mr. Gould for a lease of the shops and machinery for the purpose of establishing the business of locomotive-building. The lease was consummated in November 1869, and before the close of the year the first two locomotives of the new Brooks Locomotive Works Company were turned out. In 1883 the property, comprising 20 acres of land, the permanent plant, additions and machinery, was purchased from the New York, Lake Erie and Western Railroad Company by the Brooks Locomotive Works.

The Richmond Locomotive and Machine Company of Richmond, Va., is the only locomotive-manufacturing plant in the South. The works were established in 1865 for the manufacture of plantation and saw-mill machinery, and were gradually adapted for the construction of tram and street-car motors. In 1880, the shop having been destroyed by fire, it was removed beyond the city limits and reconstructed upon an enlarged scale. In 1889 it secured the contract from the United States government for building the machinery of the armored battleship Texas, which gave it wide prominence. This contract was successfully executed, but the works have since been devoted exclusively to the construction of locomotives.

The Dickson Manufacturing Company of Scranton, Pa., are important manufacturers of locomotives and of mining machinery, for which their location in the anthracite coal regions of Pennsylvania is most suitable. These works were established in 1862.

The Manchester Locomotive Works, of Manchester, N. H., were established in the early

1. American Locomotive of 1830.
2. American Locomotive of 1840.
3. American Locomotive of 1900.

LOCOMOTIVE AND ENGINE INDUSTRY

fifties, and were for many years under the management of Aretas Blood, who was prominent in locomotive-building in New England.

The works of H. K. Porter & Company of Pittsburgh were established in 1866, and have been devoted exclusively to the manufacture of light locomotives for special work in mills, furnaces, and mines, and for contractors' and plantation service, etc. The firm was at first Smith & Porter, and later Porter, Bell & Company.

From the foregoing it is apparent that, exclusive of such locomotives as are built in railroad shops or shops not regularly engaged in the business of locomotive-building, the locomotive-manufacturing establishments of the country have an aggregate capacity of about 3,500 locomotives a year. The demand for locomotives in each year is largely dependent upon two factors: the general prosperity of the country, which is always accompanied by a large volume of freight to be transported, bringing large earnings to the railroads; and the mileage of new lines under construction and requiring to be equipped. These two causes are really one, because many new lines are built only in times of general prosperity when capital has laid aside its usual timidity and money is seeking new channels of investment. Unfortunately business prosperity is intermittent, and during the less prosperous years the capacity of these several works to produce locomotives is largely in excess of the ability of the railroads to purchase them. The actual reported production of the past 12 years, with the number exported (not including Canada and Mexico), is as follows:

LOCOMOTIVES PRODUCED AND NUMBER EXPORTED.

YEAR	Total Production Reported	Number Exported Omitting Mexico and Canada	Remainder not Exported
1889.....	1,860	187	1,673
1890.....	2,213	137	2,076
1891.....	2,300	357	1,943
1892.....	1,764	141	1,623
1893.....	2,011	205	1,806
1894.....	695	189	506
1895.....	1,110	252	858
1896.....	1,175	261	914
1897.....	1,251	338	913
1898.....	1,875	468	1,407
1899.....	2,473	517	1,956
1900.....	3,153	525	2,628
Average.....	1,823	298	1,525

The total number of locomotives in use upon the railways of the United States, Canada, and Mexico for the same years, as reported to 'Poor's Manual,' is as follows: 1889, 30,566; 1890, 31,812; 1891, 33,563; 1892, 34,626; 1893, 36,018; 1894, 36,304; 1895, 36,610; 1896, 36,388; 1897, 36,410; 1898, 36,746; 1899, 37,245; 1900, 38,065.

As the average life of a locomotive is 20 years, an annual production of about 1,800 locomotives will supply the natural wear, while there is in the country a capacity for constructing in contract and railroad shops about twice that number. The difference between the number requiring replacement on account of natural wear and this total capacity must be absorbed

by locomotives for new lines, for permanently increased traffic, and for export. The locomotive-building establishments above mentioned employ in the aggregate 25,000 men, who receive in wages about \$15,000,000 annually. The total value of the product of these works, when operating to their full capacity, is more than \$45,000,000.

American locomotives soon attracted attention abroad. In 1845 the Baldwin Works exported locomotives to the Royal Württemberg Railroad. In 1848 Rogers shipped locomotives to Cuba; and while the exportation of locomotives during recent years has been largely to those countries without the resources requisite for locomotive-building, in the earlier years it was not uncommon for American manufacturers to ship their products to Austria, to England, and elsewhere in continental Europe. Statistics fail to show the number of locomotives exported during the earlier years, and even recent statistics are inaccurate in not covering shipments of locomotives to Canada and Mexico. During the 20 years between 1871 and 1900, there were exported 5,232 locomotives, having a valuation of \$48,797,527, to countries exclusive of those reached by rail connections from the United States. At the present time American locomotives are shipped to almost every country in the world. The extent of their exportation is shown by the following list of countries to which locomotives were shipped by the Baldwin Locomotive Works during the three years 1898, 1899, and 1900:

NORTH AND SOUTH AMERICA.

Alaska	Chile	Nicaragua
Barbados	Costa Rica	Newfoundland
Brazil	Cuba	Nova Scotia
British Columbia	Ecuador	Peru
Canada	Guatemala	Porto Rico
Colombia	Mexico	San Domingo
	Venezuela	Yucatan

EUROPE.

Algiers	England	Ireland
Bavaria	Finland	Norway
Belgium	France	Russia
Denmark	Holland	Spain
	Sweden	

ASIA.

Assam	China	Japan
Burma	India	Manchuria

AFRICA.

Algeria	Egypt	Sudan
Cape Colony	Natal	Tunis

AUSTRALIA AND NEW ZEALAND.

Hawaii	Tasmania	Western Australia
New Zealand	Victoria	

During 1808 three leading British railways purchased 80 American locomotives, of which 70 were supplied by the Baldwin and 10 by the Schenectady Works. These railways were the Midland, Great Northern, and Great Central. The reason for doing so was the great engineering strike of the previous year which caused all the engineering works of Great Britain to be overcrowded with orders and unable to meet the demands upon them. These American locomotives have been subjected to severe criticism and efforts have been made to show that they are less economical than English locomotives. No authenticated facts have, however, been produced, and the statements made have been inconclusive. Large shipments have been made to India, Egypt, and South Africa, largely because of the same reasons, which have been

LOCOMOTIVE AND ENGINE INDUSTRY

similarly attacked. The demand for American locomotives is constantly growing and further increase of the export business may be expected.

The market price of a locomotive in 1832 appears to have been \$4,000, this sum having been agreed upon between Matthias W. Baldwin and the Philadelphia, Germantown and Norristown Railroad for the locomotive Old Ironsides. The highest prices known in locomotive-building, as in other industries, were those obtained during the Civil War, when heavy freight or passenger locomotives commanded from \$30,000 to \$35,000. Prices declined after the close of the War to about \$7,000 for a 35-ton passenger locomotive in 1878-9. During the so-called boom of 1880-1, prices again rose to about \$15,000 each for similar passenger locomotives; but since that time there has been a constant reduction in the price per pound, the weights of locomotives gradually increasing with the demands of increasing traffic, while prices remained nearly stationary until 1896 at about \$8,000 to \$9,000 each for average passenger locomotives, and from \$9,000 to \$10,000 each for average freight locomotives.

In 1897, with the introduction of the 50-ton steel car, a further considerable advance began in the weight and power of locomotives. The ordinary weight of Consolidation freight locomotives, which had been from 60 to 70 tons, was increased to 80 to 100 tons, and a number were constructed as heavy as 115 tons (of 2,000 pounds) exclusive of tender. The extraordinary business activity which began in 1898 increased the earnings of railroads and therefore their purchasing power. On this account and on account of the heavier classes of locomotives introduced and on account of higher costs of materials and labor, the average price of freight locomotives advanced to about \$15,000 or \$16,000, and the average price of passenger locomotives to almost the same figures. The demand for power sufficient to handle heavy trains at sustained high speeds, capable of accelerating speed rapidly after starting caused the introduction of heavier types of passenger locomotives. The eight-wheel or American type became inadequate to these increased demands, and the ten-wheel engine, except for heavy grades, involved the disadvantages of comparatively small driving wheels, an unsatisfactory form of firebox, an adhesion altogether in excess of actual requirements under ordinary conditions, and excessive resistance within the machine itself. To meet these objections the Atlantic type was brought out by the Baldwin Locomotive Works. It is substantially a ten-wheel locomotive with very large driving-wheels, and the rear pair of driving-wheels replaced by a pair of trailing wheels. The lower side of the trailing wheels permits of a deep firebox of large grate and large cubic area for thorough combustion. An enormous boiler capacity is available in proportion to the adhesion. The driving-wheels are closely coupled and the total wheel-base is long enough to give great smoothness of motion at high speed, and is sufficiently flexible.

The importance of fuel economy was appreciated in Europe earlier than in the United States. Progress had been made in the development of the compound locomotive by Lindner, Von Borries, La Page, Worsdell, Webb, and others. W. S. Hudson, superintendent of the

Rogers Locomotive Works, designed a two-cylinder, or cross-compound, locomotive, as early as 1873, but it was never built. In 1882 Henry D. Dunbar designed and patented a four-cylinder tandem compound locomotive, which was tested on the Boston and Albany Railroad. In 1889 the Pennsylvania Railroad imported from England a compound locomotive of Webb's pattern for experimental service. The same year Samuel M. Vauclain, superintendent of the Baldwin Locomotive Works, designed a four-cylinder compound locomotive, in which a high-pressure and a low-pressure cylinder are placed one above the other on each side of the locomotive, both formed within a single casting, together with the steam-chest, and occupying the same place as the ordinary single-expansion cylinders. The two piston-rods connect to a common cross-head, but back of the cross-head pin there is no essential difference from the ordinary engine. About the same time A. J. Pitkin, superintendent of the Schenectady Locomotive Works, brought out a two-cylinder, or cross-compound, locomotive, having a form of intercepting-valve differing from those previously used abroad. The general interest in compound locomotives, together with the powerful influence of two of the most prominent works in the country, led to the rapid introduction of compound locomotives, and caused other locomotive-builders to bring out similar designs. There have since been built in the United States about 3,500 compound locomotives, of which more than 3,000 are of the Vauclain pattern, some are of the four-cylinder "tandem" type, and most of the remainder are of the two-cylinder or cross-compound type. The compound locomotive is unquestionably a step in advance, realizing an economy of 15 to 40 per cent, according to the service in which it is employed.

The most conspicuous improvement in transportation, which resulted from the introduction of steam-power, was the great increase in the capacity for high speed. Peter Cooper's first locomotive is said to have attained a speed of 18 miles per hour. Baldwin's Old Ironsides is recorded as having attained a speed of 60 miles per hour for a short distance. Speeds of 60 miles per hour have therefore been known from the early days of American railways. The real progress of locomotive development has not been so marked in increasing the capacity for speed as in increasing the weight of trains which can be hauled with certainty at rates of speed which have previously been regarded as phenomenal. Up to 1889, when the compound system was introduced, there did not exist a demand for sustained speeds exceeding 50 miles an hour. In November 1892, one of Vauclain's compounds, No. 385, running on the Philadelphia and Reading and the Jersey Central railroads, between Philadelphia and Jersey City, with a train of four heavy cars, attained a speed of 97 miles per hour by covering one mile in 37 seconds. On 10 May 1893, locomotive No. 999, of the New York Central Railroad, covered a mile in 32 seconds, equivalent to 112½ miles an hour, hauling the Empire State express, consisting of four heavy cars. On 19 July 1893 engine No. 682, a Vauclain compound, of the Philadelphia and Reading Railroad, hauled a train of nine loaded passenger cars from Winslow Junction to Pleasantville, 26 miles, in 22 minutes, or at the rate of 70.9 miles per hour, and on 27 August,

LOCOMOTIVE AND ENGINE INDUSTRY

the same locomotive hauled 17 loaded passenger cars over the same distance in 27 minutes, or at the rate of 57 miles per hour. These performances are remarkable for the weight of the trains hauled. On 11 Sept. 1895, a locomotive of the New York Central and Hudson River Railroad hauled the Empire State express, consisting of four cars, from New York to East Buffalo, 436½ miles, in 407½ minutes, being an average speed of 64.26 miles per hour. Beginning with the summer of 1896 the Philadelphia & Reading Railroad operated during the months of July and August a train of five and six passenger cars between Camden and Atlantic City, 55½ miles, in 48 minutes. These runs have been made with great regularity. The locomotives used are Atlantic type, Vauclain compounds, with Wootten boilers and 84-inch driving-wheels. It is believed that the steam locomotives of to-day possess capacity for running at as high a speed as is required by public demand, or as is consistent with the commercial conditions governing the business of transportation.

During the past few years the general substitution of electric power for horse-power and for other means of propulsion on tramway lines has caused electricity to be regarded as perhaps a rival of steam, or at least as a competitor which may prove to be a serious rival in the future. The progress of electrical science is so rapid that what is written to-day is obsolete tomorrow. What we regard as impossibilities now may shortly become established facts. In 1840 Davis & Cook constructed a walking-beam engine with a zinc and copper battery, using a solution of blue vitriol. In 1842 Davidson, of Scotland, constructed a five-ton electric locomotive, which was actuated by 78 pairs of 13-inch-square zinc and iron plates in sulphuric-acid solution, and propelled itself at the rate of four miles an hour. In 1844 Channing conceived the idea of substituting electro-magnets for permanent steel magnets, and of exciting the field magnets by an electro-magnetic machine. This idea was subsequently developed by Henry Wilde, Manchester, England, between 1863 and 1866. In 1847 Farmer constructed an electro-magnetic locomotive having 48 pint cup cells of Grove nitric-acid batteries, which drew a car containing two passengers on a track of 18 inches gauge. In 1850 Page, of Washington, constructed an electro-magnetic locomotive of 16 horse-power, actuated by 100 cells of Grove nitric-acid batteries, having platinum plates 11 inches square. This machine propelled a car carrying a dozen or more persons on the Baltimore and Washington Railroad, at a speed of 19 miles an hour. In 1851 Thomas Hall, of Boston, constructed and exhibited a small electric locomotive taking its current from a stationary battery by means of the rails and wheels, and arranged automatically to change the current and return at the end of the track. In 1860 he made a more elaborate model called the Volta, which was exhibited at the American Mechanics' Fair. In 1859 Farmer invented what he designated the self-exciting dynamo, which was constructed in 1860. Improvements on this were made by Wheatstone, Leaman, and Ladd in 1867, and by Gramme in 1871. It made possible the substitution of the dynamo for the galvanic battery, and permitted the generation of electricity at low cost. The first experiments in the use of

electrical locomotives on steam roads appear to have been made by Leo Daft on the New York Elevated Railroad with a motor of 12½ horse-power. In 1886 Frank J. Sprague conducted experiments on the same road with trains of individual motor-cars. In 1891-2 the Thomson-Houston Electric Company built a locomotive of about 125 horse-power for freight service at Whitinsville, Mass. This locomotive handles an aggregate load of 200 to 300 tons at a speed of five miles an hour. In 1892 the North American Company ordered from the Baldwin Locomotive Works a powerful electric locomotive to be constructed from the plans of Sprague, Duncan & Hutchinson Company, Limited. This locomotive was completed in 1894 and weighed 67 tons. It had four pairs of wheels connected by coupling-rods, and the field magnets were hung from the driving-boxes, while the armature was hung on the driving-axle. In 1892 the General Electric Company undertook the construction of an electric locomotive for the tunnel of the Baltimore and Ohio Railroad in Baltimore. This locomotive was completed in 1895, and was designed to weigh 90 tons and develop 1,500 horse-power. In 1892-3 the General Electric Company equipped in the grounds of the World's Columbian Exposition at Chicago, and operated during the period of the Exposition in 1893, an elevated railroad known as the Intramural Railway. Its mechanical success was such that in 1894 the Metropolitan West Side Elevated Railroad, which had been designed as a steam line, countermanded an order for 25 steam locomotives and substituted electric power. In 1895 the Lake Street Elevated Railroad of Chicago discontinued the use of steam locomotives and substituted electric power. The same year the New York, New Haven and Hartford Railroad equipped its Nantasket Beach branch electrically for experimental purposes, and the Pennsylvania Railroad equipped a branch road at Mt. Holly for the same purpose. In 1895 the Baldwin Locomotive Works consummated a working agreement with the Westinghouse Electric and Manufacturing Company, for the production of electric equipment for railway service. Large numbers of electric locomotives have been constructed for mine haulage, and for handling freight in industrial establishments. Electric tramways are operated in every city and town, while traction lines, some of such substantial construction as to resemble railways, are rapidly developing throughout the country. Electricity has become recognized as the only suitable power for operating elevated railroads in cities. The Manhattan Railway in New York has installed electric traction, and American enterprise is electrically equipping several lines in the city of London. There is a large field for electricity in railway work, and it is probable that after it has been applied to switching and suburban service in the great cities, public opinion will compel the abandonment of steam locomotives in these precincts.

Although the steam locomotive is more prominently brought to the attention of the public, and is therefore more popular and better known, yet it has no greater effect on daily life than other steam-engines. Mention has been made of steam-power applied to transportation in navigation on the ocean and on inland waterways, but besides this use for steam it supplies a

LOCOMOTIVE AND ENGINE INDUSTRY

thousand wants of daily life, such as the furnishing of the water-supply of great cities, the driving of industrial machinery, the lighting of streets and houses, the running of elevators in high modern buildings, the extinguishing of fires, and the operating of the electric tram-car. For many years the development of the stationary engine and the marine engine were identical. The first experimental steam-engine built in the United States is said to have been constructed in 1773 by Christopher Colles, a lecturer before the American Philosophical Society at Philadelphia. In 1787 John Fitch launched on the Delaware River at Philadelphia a steam-boat propelled by paddles, which attained a speed of 13 miles per hour, and in 1796 he experimented in New York with one operated by a screw. His efforts were closely followed by those of Robert Livingston. About the same time other mechanics were devoting attention to the problem of steam navigation, among them Samuel Morey, Nathan Read, Nicholas Roosevelt, Oliver Evans, Robert Fulton, John Stevens, and others. Transatlantic steam navigation began in the year 1819, when the American steamer Savannah made the trip from Savannah to St. Petersburg. The development of the marine engine through its various forms of single expansion, compound, and triple expansion cylinders has resulted in the powerful mechanisms which drive the St. Louis, the St. Paul, the Oceanic, the Deutschland, and the Kronprinz Wilhelm at the rate of 500 to 600 miles per day. This development has resulted from the labors of many, among whom may be mentioned John and Robert Stevens, Robert Thurston, James P. Alair, the Copelands, and John Ericsson. Since 1850 the improvements have been rather in details of construction than in any marked change in type. The engineer has striven and is still striving for the highest efficiency with the greatest degree of economy. The introduction of what is known as the Corliss valve gear marks probably one of the greatest eras in engine building. This is a device by which the steam is admitted into the cylinder for any desired portion of the stroke, and the point of cut-off automatically maintained by the governor without affecting in the least the free opening of the exhaust. Many devices had been introduced before this time for the purpose of using the steam expansively, among which may be mentioned that of Frederick E. Sickles, in 1841, whose drop cut-off with detachable valve gear was used in this country until 1849, when George H. Corliss brought out the improved expansion gear which bears his name, and which is used to-day by builders all over the country. The adoption of the surface condenser may also be noted as an improvement of great practical utility in the economy of that class of engines to which it is adapted.

As the country developed, there was an ever-increasing call for smaller engines with higher speed and higher steam pressure. Excessively high pressures had already been experimented with as early as 1823 by Jacob Perkins, who in 1827 constructed a single-acting engine in which steam of 800 pounds pressure was used, and in the same year he made a compound on the Wolfe plan, in which he adopted a pressure of 1,400 pounds, expanded eight times. He even went so far as to propose to adopt a pressure of 2,000 pounds, using engines with small cylinder

dimension and cutting off the admission at one sixteenth of the stroke. For obvious reasons these excessive pressures were not adopted in general practice, but the experiments had the effect in later years of calling the attention of builders to the greater economy of high pressure steam, and engines and boilers were adapted to its use in a moderate degree. This caused inventors to consider different plans by which high pressures could be utilized and high speed engines constructed. A number of designs were executed, among which may be noted the Westinghouse, which is a double-cylinder, single-acting engine. The low cost and simplicity, combined with a high degree of efficiency, have brought this engine into extensive use.

The steam turbine has recently attracted much attention on account of its remarkable steam economy and wide range of load. The force of the steam is converted into work through the impact and reaction due to its velocity, which is increased by liberation and expansion. The advantages obtained over the ordinary steam engine are the continuous rotative action, and the absence of dead centres and consequent mechanical complications, and the absence of the strains suddenly applied and reversed which are unavoidable in a reciprocating engine. Two systems are, at present, in use, the De Laval and the Parsons. The former is on the principle of the axial jet turbine water wheel, the jet of steam being brought in contact with the blades of the turbine wheel, at the proper angle, and passing through to the discharge. In order to obtain the greatest effect, it is necessary that the turbine attain a high velocity, sometimes 30,000 revolutions a minute. This excessive speed is reduced to the normal by a specially designed system of gearing. The Parsons steam turbine is manufactured by the Westinghouse Machine Company, and it differs from the De Laval system in that the main armature or drum can be run at a lower rate of speed with economical results. The cylindrical steam chamber is of varying internal diameter and provided with numerous rows of curved guide plates or vanes. Central drums of correspondingly varying diameter, on which are secured similar rows of blades spaced to fit between the stationary rows, form the rotating portion, and its shaft may be coupled direct to the armature of a dynamo or receive a pulley for belt drive. The stationary rows of blades serve to guide the steam in the proper direction for doing its work upon the movable ones. The steam is introduced at the small end of the chamber and acts first upon the smaller set of blades; from this it is expanded into the larger portion of the chamber and acts upon the next larger set of blades and so on throughout the series. By this arrangement which increases the diameter of the rotating parts, the speed of the shaft is reduced and the necessity of back gearing is avoided.

Much attention is likewise being directed to the economies available by the gas-engine. Such engines are now working in units of upward of 700 horse-power and, using gas prepared in special generators, give favorable indications of effecting further important economies in the conversion of heat into power.

The competition among engine builders has caused marked changes to be made in simplifying and reducing the cost of manufacture. Probably no change which has been made equals that

LOCOMOTIVES

adopted by nearly all builders of what may be called the merchantable engine, of reducing the number of main parts to a single column or bedplate, in which the revolving and reciprocating parts are supported and the cylinder secured directly to this column or bed. Engines of this class, both vertical and horizontal, are manufactured by builders all over the country, and perhaps no better estimate can be derived of the advance in this particular than to consider that in 1795 there were exceedingly few in this country who were interested in the introduction of the steam-engine, whereas now scarcely a town of any importance exists which does not boast of one or more shops where steam-engines are built. The marked advance in the efficiency of the steam-engine may be seen when we consider that previous to 1850 it took from 5 to 8 pounds of coal and something like 80 pounds of water per horse-power per hour to operate what was then considered the best class of engine, whereas to-day the same work is done with an expenditure of 1.8 pounds of coal and 15 pounds of water per horse-power per hour. The manufacture of stationary engines is so widely distributed and so extensively followed that neither in the United States census nor in other compilations of statistics is it possible to determine the number of men employed, the number of employers interested, the amount of capital involved, or the value of the productions of this branch of engine-building.

The steam fire-engine is an important factor in securing the safety of human life and property, and the improvement in such engines within fifty years has been great. Captain John Ericsson built a portable steam fire-engine, which was tested in New York city in 1842, but was not put into regular service. The time required for raising steam was then eighteen minutes. Steam fire-engines were put into permanent service in Cincinnati about 1853, and at that time steam could be raised in less than four minutes from the time the torch was applied. Economy is not a matter of prime importance in steam fire-engines, the first requisites being power and portability. Modern machines of beautiful design and superb workmanship can be drawn by two horses, and can be made ready for delivering enormous quantities of water within three minutes after the sound of the alarm. This comparatively small apparatus can throw a stream of water over all except the highest buildings in the large cities, and can run for hours without damage. The boiler of the steam fire-engine is one of the most powerful for its weight used in any practical work. The fire-engines manufactured in the United States are admittedly superior to those manufactured elsewhere. (See FIRE PROTECTION.) This superiority has doubtless resulted from the need of the most efficient apparatus to protect cities largely built of wood, and which are much more subject to conflagration than those of older countries, where brick and stone are the principal materials used in construction.

Other important branches of the industry are the manufacture of steam road-rollers and of motor vehicles. See AUTOMOBILES.

While the progress of steam-engineering during one hundred years has largely revolutionized the methods of living, this development has not reached its termination. On the contrary, the engines and boilers which have recently been

used in torpedo-boats, the experiments of Maxim in England, and of Langley in the United States, introducing steam-engines and boilers of power heretofore inconceivable for their lightness, and the light engines and boilers which are used in road carriages, indicate that we may expect in the near future an enormous saving in the amount of coal used in producing power, and in the convenient subdivision of power for a great variety of uses. It is reasonable, therefore, to expect that this advance will continue at an accelerated pace, and it may be predicted that the further development of steam engineering will result in the increased conservation of the world's resources and in an added contribution to the comfort and happiness of mankind.

ALBA B. JOHNSON,
Baldwin Locomotive Works.

Locomotives, Compound. The compound locomotive, like the compound stationary engine, is designed to save fuel by requiring less steam to do a given amount of work. A compound locomotive is not necessarily any more powerful, nor any faster, than a simple engine, but will do the same work with less coal and for less money. A compound locomotive, however, may be both faster and more powerful than a simple engine for the reason that as the compound uses less steam (q.v.) doing the same work, the same boiler that supplies a simple engine will do more work with compound cylinders.

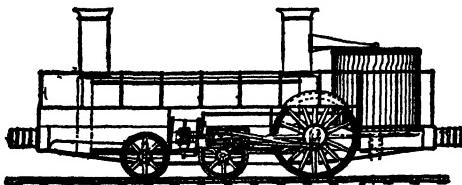

The principle of compounding steam cylinders is to let the exhaust from the high pressure cylinder go to the low pressure and drive that before escaping to the atmosphere. This is done to divide the expansion between the two cylinders instead of doing it in one, the aim being to avoid excessive condensation. Steam at 200 pounds gauge pressure per square inch is at a temperature of 387 degrees, while the back pressure or pressure of the steam that is being pushed out of the cylinder by the returning piston will average about 5 pounds or 227 degrees. The steam then would expand from 200 down to 5 pounds or a difference of 160 degrees of heat. The cylinder cools down with the steam (though not so rapidly) and, presenting a comparatively cool surface to the next admission of steam, condenses a portion of it. The heat from the condensed steam goes to warm the walls of the cylinder which are again cooled by the expansion.

The ideal compound locomotive seems to be one that can be used either simple or compound at any time or for any length of time at the will of the engineer. When used in either condition it should be of equal power on each side, and when running simple should be as economical as any simple engine under the same conditions. It should of course only be used simple in starting or in getting a train over a bad part of the road. The engine should not be worked simple any more than necessary, as in the compound position it is saving the fuel. Nor should an engine working compound be hooked up to cut off as short as in working simple.

The first compound locomotive of which we have record is that of Thomas Craddock who began experimenting in April 1844. In his book, 'The Chemistry of the Steam Engine,' published in London in 1848, he proclaims the superiority of the compounding feature and de-

LOCOMOTIVES

scribes an engine in which "one eccentric, one valve, one crosshead, one connecting rod and one steam box serve both cylinders." He evidently abandoned this, as in the engine shown

Compound Locomotive of Thomas Craddock. 1848.

he used two crossheads and two connecting rods, although he used but one valve. He also used a fan condenser as will be seen, and claimed a vacuum of 24 inches. The cylinders of this engine were 6 and 14 inches respectively, or a ratio of 1 to 5.4. Another plan of his was also shown, but there is no record of its having been built. He used 115 pounds of steam, but predicted the use of 200 pounds in the nearer future than it was realized. His patent was dated 3 Dec. 1846. Other early inventors were: John Nicholson, James Samuels and Frazer Selby, all English.

The first American compound locomotive was built at the Shepard Iron Works, in Buffalo, from the designs of Perry & Lay in 1867. A switching engine of the Erie Railroad had their tandem cylinders placed on it. This engine worked nicely and ran for several years, but coal economy was still a question of the future, and as it was ahead of its time, the idea was abandoned. The next compound was of the two-cylinder type and was built in 1870 by the Remington Arms Company, at Ilion, N. Y., from the design of William Baxter. This was used on a suburban road, the Worcester and Shrewsbury, and gave good service. It has an intercepting valve under control of the engineer, and could be run as a simple engine any length of time. On 11 March 1873, a patent was granted William S. Hudson, of the Rogers Locomotive Works, Paterson, N. J., for a superheater in smoke-box, so arranged as to reheat the steam passing from high pressure to low pressure cylinders of a two-cylinder compound. This is sometimes cited as the first two-cylinder compound, but in reality none were built, and it was preceded by others as we have seen. About this time the compound began to excite more interest both in England and on the Continent. Prominent among them were Anatole M. Mallet, Francis William Webb, August Von Borries and Robert Lindner.

This brings us to the later American designs, with which we are most interested. On 25 June 1880 a patent was granted to Samuel M. Vauclain, of Philadelphia, for a four-cylinder type of engine. Cylinders were parallel and connected to one crosshead. One patent shows two piston valves, another shows but one, which is the style now used and known as either the "Vauclain" or "Baldwin" type. It is rather a curious matter of patent history that on 18 June 1889, one week earlier, Joseph Lewis, of South Evanston, Ill., obtained a patent for a similar engine, except that the one piston valve was rotated by gearing instead of being a reciprocating valve. This engine has never been in service, however.

On 10 Dec. 1889 Albert J. Pitkin obtained his patent on what is now known as the Schenectady compound. As first built it went into compound automatically and could not be run as a simple engine except at the start, but this has been modified so as to make it optional with the engineer. On 27 May 1890 Henry F. Colvin, of Philadelphia, obtained a patent on the application of an automatic reducing valve to admit live steam to low pressure cylinder just in proportion to ratio of cylinders, so as to keep the total power on each side equal. This engine was built by the Pittsburg Locomotive Works. The Pittsburg compound has the intercepting valve on the high pressure side and it is not moved to compound automatically, but is moved independent of pressure in the receiver. It can be run simple any length of time (as is now common with them all), but this and the Rhode Island were the first to have this feature, except the Baxter before mentioned. In starting, the high pressure cylinder receives steam as usual, and the steam for the low goes through the reducing valve into the receiver, a separate passage being provided for the high pressure. Moving the valve into compound position shuts the live steam from the receiver and closes the independent exhaust of the high pressure cylinder and turns it into the receiver to the low.

The late C. H. Batchellor patented what is known as the Rhode Island compound on 22 Sept. 1891. This was similar to the Pittsburg engine in some ways, but had the intercepting valve on the low pressure side and goes into the compound automatically by an accumulation of reserve pressure. The Richmond compound (Mellin System) has the intercepting valve on the low pressure side, and is moved automatically by the receiver pressure.

The Richmond engine was the first to use an overpass valve. With an engine running without steam or "drifting" as railroad men call it, the cylinders become air-pumps. The air forced out drafts the fire at a time when it is not needed, and on mountainous roads cuts quite a figure in coal consumption. While this is present in any engine, it is aggravated in the large cylinder of a compound, and is usually met by the use of a vacuum valve at each end of the cylinder. These admit air and do not overcome the needless draft on fire. It is often charged that two-cylinder compounds "nose" around on account of developing more power on one side than the other, but this would seem to be largely imagination. A simple engine is always working one-sided in so far as one side is at maximum while the other is a minimum power, and it is nothing out of the usual to bring an engine in with one side uncoupled, the other doing all the work. The fallacy of one-sided working when running simple on account of large cylinders is shown by the action of reducing valve and the fact that careful tests show a variation of less than 2 per cent with careful designing. This is no more than is apt to be found on any engine after having its cylinders bored larger than the other—being simply trued up. The fact that a compound engine has more power when working simple than in compound is generally taken as showing that the reducing valve does not act quickly and the large cylinder gets more than its proportion of steam. That this is not the case we learn that the safety valve in the receiver passage—set to

OPERATION OF LEADING COMPOUND LOCOMOTIVES

Pittsburg Compound — simple.

LOCOMOTOR ATAXIA — LOCUST TREES

blow at the determined receiver pressure—rarely or never pops. The actual reason is that the high pressure cylinder is relieved by its back pressure, which adds quite a little to the effective forward pressure.

The last few years has brought the tandem compound to the front after the lines of Perry and Lay in 1867. These are the Schenectady, the Colvin-Wightman and the Baldwin. They are very heavy and powerful engines and are capable of heavy work. They are necessarily heavy in front and some of them are very inconvenient to get at and repair. This, however, is more the fault of the designer than the type. The balanced engine, too, is coming to the front, with one set of cylinders driving the wheels from the outside and the other by cranked axles on the inside. They are a development of the old Shaw and Strong locomotives. In France this is known as the DeGlehn type.

The points to be considered by the mechanical engineer, as in any case, are the construction from a mechanical point of view, the number of parts, their strength or delicacy, and the likelihood of failure. Also the number of ground joints, if any, and the result if they are not kept tight. As it is a simple case of dollars and cents, the additional first cost and cost of repairs as compared with a simple engine must be weighed against the fuel economy. If the net results were not satisfactory, the compound would not be increasing in use as rapidly as it is at present. That the compound locomotive has come to stay and is doing good work there is no doubt, in spite of the opposition in some quarters, and a fuel saving of from 10 to 30 per cent is being obtained in nearly every instance. Neither is the cost of repairs necessarily high. For a more detailed history of the compound locomotive, consult the Reports of the Franklin Institute on the subject.

FRED H. COLVIN, M. E.,

Author of 'American Compound Locomotives.'

Locomotor Ataxia, a disease of the nervous system, usually occurring in adults from 40 to 50, and characterized by pain, inability to walk, and by progressive weakness which leads finally to death. The malady is long drawn out, and while not entailing, as a rule, a great amount of physical pain, causes extreme inconvenience to the patient. In the vast majority of patients it first shows itself by neuralgic pains of the lower extremities. Thus, there may be acute darting and lightning-like pains, lasting from half an hour to an hour or two, about the ankles, in the instep, shooting up the leg, or in the thighs. Occasionally these pains are present in the arms and trunk. They are frequently diagnosed as neuralgia, and it is not until development of the symptoms of ataxia (q.v.)—inability to walk in the dark, and to place the foot or hand where the mind wishes it to be placed—that the true nature of the constant neuralgic pains is recognized. With the gradual development of the inability to walk there may be a number of other symptoms—acute, lightning-like pains in the stomach, intense, sometimes acute, pain in the bladder, sometimes loss of voice, etc. There may be patches of anesthesia over the body and there is usually progressive muscular weakness. Loss of knee-jerks is an important early sign.

Associated with ataxia of the legs, which prevents the patient from walking readily in

the dark, or up and down stairs, there may be some ataxia in the hands, whereby the finer movements of buttoning the clothing, of writing, etc., may be interfered with. A very constant and usually a very early sign of locomotor ataxia consists in certain changes in the reactions of the pupil of the eye to light. This symptom is technically known as the Argyll-Robertson pupil, and shows a fixed pupil when exposed to the influence of light, but a pupil that dilates or contracts normally when tested for its powers of accommodation. Thus the pupils of a patient who has this symptom contract on looking at a near object and dilate on looking at a far object; but if a candle or beam of light is thrown suddenly on the eye, normal quick contraction of the pupil is diminished or absent. The Argyll-Robertson pupil is sometimes found as early as the neuralgias, and a diagnosis may often be made on that alone.

The progress of the disease is usually very slow; remissions occur, which give great hope to the patient and afford ample opportunities for all forms of charlatanism; but the final outcome is usually hopeless. Many conditions of the spinal cord are known in which some of the symptoms of locomotor ataxia are present, chronic neuritis from alcoholism being one. As many of these are recoverable, the diagnosis of locomotor ataxia is an extremely difficult one, and can be made only by the competent specialist. Consult: Starr, 'Organic Nervous Diseases' (1903); Marie, 'Maladies de la Moelle.'

Lo'cris, the parts of ancient Greece inhabited and named after the Locrians, the oldest Grecian peoples. There were four branches—the Epicnemidian, the Opuntian, Ozolian, and Epizephyrian Locrians, the last a colony from the Ozolian stock, living in Lower Italy. Their capital, Locri, was one of the most powerful, splendid, and wealthy cities of Magna Græcia.

Lo'cus, in mathematics, when the conditions of a problem are not sufficient to determine the absolute position of a point, but restrict it to a certain line (or lines), this line is called the locus of the point. Thus, if the base and area of a triangle are given, the locus of the vertex is a straight line parallel to the base; or if the distance of a point from another point is in a given ratio to its distance from a given fixed line, the locus of the point is a conic section.

Lo'cust. See GRASSHOPPERS; CICADA.

Locust Trees, a genus (*Robinia*) of leguminous trees and shrubs. The species have odd-pinnate leaves; pea-like flowers in drooping racemes; and pods containing several bean-like seeds. They are all useful for ornamental planting, and one species, *R. pseudacacia*, is highly valued for its timber. This species, which is the best known, and is also called false acacia and black locust, is the largest of its genus, attaining heights exceeding 75 feet and girths greater than eight feet in the rich alluvial soils of Tennessee and Kentucky. Its hard, tough, close-grained yellow wood is especially useful for ship-building, fence-posts, and other purposes in which great durability is required. It is also employed for making cog-wheels, tree-nails, for the interior finish of houses, for furniture and other uses where a highly polished wood is needed. It is the favorite material for policemen's clubs, not only because of its weight and toughness, when

LOEWE—LOG

material has also been advanced with respect to deposits in the United States; but the general opinion of geologists favors the theory of aqueous origin for the whole formation. Consult: Sixth Annual Report of the United States Geological Survey (1888); Chamberlin and Salisbury, 'The Driftless Area of the Upper Mississippi Valley'; McGee, 'The Pleistocene History of Northeastern Iowa,' in the United States Geological Survey, Eleventh Annual Report (1891); Geikie, 'Prehistoric Europe' (1881).

Loewe, Wilhelm (also called Loewe-KALLE), German politician: b. Olvenstedt, near Magdeburg 1814; d. 1886. He was educated at Halle, and adopted the medical profession. Elected in 1848 to the Frankfort Parliament, he acted with the extreme party of democracy; became first vice-president of the Parliament; and later, at Stuttgart, was its president. Charged with sedition in this, which was considered a revolutionary procedure, and once acquitted, he was nevertheless sentenced to life imprisonment for contumacy. After some years in Switzerland, France, and England, he came to this country, and for eight years practised medicine in New York. Availing himself of the amnesty in 1861, he returned to Germany, and in 1863 was elected to the Prussian House of Deputies. Four years later he was a Progressist member of the North German Reichstag. Disagreeing with his party in 1874, on the military law, he attempted to form a new Liberal party. In the elections of 1881 he lost his seat.

Loewenthal, lē-vē-tal, Henry, American journalist: b. New York 15 May 1853. Trained in the public schools and the College of New York, he studied law at the Columbia College Law School, taking his degree in 1875. He began newspaper work on the New York *Tribune* as reporter in 1872. In 1875 he was appointed law reporter on the New York *Times* and acting city editor in 1878. In 1879 to 1893 he was city editor, and from 1873 to 1896 had charge of real estate matters. In August 1896 he became managing editor, a position he now (1903) holds.

Loewy, lē-vē', Maurice, French astronomer: b. Vienna 1833. He studied astronomy and was given a position in the observatory at Paris by Leverrier, and after the latter's death assisted Mouchez in the observatory of Montsouris. He is noted for his invention of the *Equatorial-coude*, or Elbow-equatorial, in which the observer remains seated at the upper end of the polar axis of the telescope, as if working with a microscope on a table, with the means of directing his view to any part of the heavens under his control. He also devised improved methods of determining the constants of astronomical refraction and aberration.

Lofoten, lō-fō'ten, or Lofodden, Norway, a group of islands off the northwest coast, stretching southwest to northeast about 175 miles. The largest are Andoen, Langoen, Hindoen, East and West Vaagen, and Flagstadöe. They have bold, precipitous, rugged, and deeply indented coasts, and an elevated, sterile interior, several containing mountains which, though not lofty, are covered with perpetual snow. Immense shoals of cod and herring frequent their shores, and extensive and valuable fisheries are

carried on. The principal cod-fishery beginning January–February, ends in April, but the herring-fishery continues, and furnishes an important branch of national revenue. In ordinary years about 4,000 boats, each manned by five hands, are employed. The celebrated whirlpool, the Maelstrom, is situated at the southern extremity of these islands. Permanent population of group, about 20,000.

Lof'tie, William John, Irish Anglican clergyman, writer on antiquities: b. Tandragee, County Armagh, 25 July 1839. He was educated at Trinity College, Dublin, and after holding temporary Church appointments, became assistant minister of the Chapel Royal, Savoy, in 1871. He joined the staff of the 'Saturday Review,' and in 1894 that of the 'National Observer.' As a writer on antiquarian subjects he successfully combines learning and picturesque statement. He has published, 'Round About London' (1877; 4th ed. 1880); 'Plea for Art in the House' (1877); 'Memorials of the Savoy' (1879); 'A Ride in Egypt' (1879); 'A History of London' (1883); 'Authorized Guide to the Tower of London' (1886); 'London' (1887); 'Windsor' (1887); 'Westminster Abbey' (1890); 'The Cathedral Churches of England' (1892); 'Inigo Jones and Wren' (1893); 'Inns of Court and Chancery' (1894); 'London Afternoons' (1901); etc.

Lof'tus, Augustus William Frederick Spencer, English diplomatist: b. 4 Oct. 1817; d. 9 March 1904. He entered the diplomatic service in 1837 as attaché at Berlin and was likewise attaché at Stuttgart in 1844. He was secretary to Stratford Canning in 1848, and after serving as secretary of legation at Stuttgart (1852), and Berlin (1853), was envoy at Vienna (1858), Berlin (1860) and Munich (1862); became ambassador at Berlin 1865, to the North German Confederation 1868–71, and to Saint Petersburg 1871–9. He was governor of New South Wales 1879–85. He published 'The Diplomatic Reminiscences of Lord Augustus Loftus' (1892–4).

Log, an apparatus used to measure the rate of a ship's velocity through the water. For this purpose there are several inventions, but the one most generally used is the following, called the common log. It is a piece of thin board, forming the quadrant of a circle of about 6 inches radius, and balanced by a small plate of lead, nailed on the circular part, so as to swim perpendicularly in the water, with the greater part immersed. The log-line is fastened to the log by means of two legs, one of which is knotted, through a hole at one corner, while the other is attached to a pin fixed in a hole at the other corner, so as to draw out when sufficient force is exerted on it. The log-line, being divided by means of knots of colored cloth into certain lengths, which are in proportion to an equal number of geographical miles, as a half or quarter minute is to an hour of time, is wound about a reel. The whole is employed to measure the ship's head-way in the following manner: — The reel being held by one man, and the half-minute glass by another, the mate of the watch fixes the pin and throws the log over the stern, which, swimming perpendicularly, feels an immediate resistance, and is considered as fixed, the line being slackened over the stern

LOG-BOOK—LOGAN

to prevent the pin coming out. The knots are measured from a mark on the line at the distance of 12 or 15 fathoms from the log. The part of the line between the log and this mark is called the *stray-line*. The glass is turned at the instant that the mark passes over the stern, and as soon as the sand in the glass is run out the line is stopped. The water then pressing on the log dislodges the pin, so that the board, now presenting only its edge to the water, is easily drawn aboard. The number of knots and fathoms which had run off at the expiration of the glass determines the ship's velocity.

Log-book, a book in which are officially recorded the proceedings on board a ship. In it the contents of the log-board are daily transcribed at noon, together with every circumstance deserving notice that may happen to the ship or within her cognizance, either at sea or in a harbor, etc. In addition to the weather, speed, astronomical observations, etc., the entries required to be made include convictions, offenses, punishments, conduct of crew, illnesses and injuries, deaths, births, and marriages, quitting the ship, wages of men entering the navy, wages of deceased seamen, sale of deceased seamen's effects, collisions—in short, every condition, occurrence, and transaction which comes under official notice. The log-book must be signed by master and mate, and certain other persons in particular cases.

Log Cabin and Hard Cider, a term used in American politics in the campaign of 1840. The Whig candidate for President, William Henry Harrison, was a military man of plain manners. One of the Democratic papers, scoffing at the Whigs for taking a candidate not of the first caliber, advised that Harrison be given a log cabin and a barrel of hard cider, and he would stay contentedly in Ohio. This was taken up by the Whigs, and really helped to make their candidate popular with the masses. Log cabins were erected in great numbers in the cities, and were carried in processions, accompanied with barrels of cider.

Log-rolling, in American politics, a term used for maneuvers of politicians, by which they seek to secure co-operation in carrying favorite measures through legislatures and other bodies. Generally log-rolling is employed by individuals who approach others in support of personal schemes and interests. The word was formerly very popular in the United States, but has become almost obsolete, being supplanted by the term "button-holing."

Logœdic (lög-a-ë'dik) **Verse**, in Greek and Latin poetry, a rhythm in $\frac{3}{4}$ time; now obsolete and are rarely found except in imitations of classic lyric measures. See METRE; RHYME.

Logan, lög'gan, English name of the American Indian chief Tah-gah-jute: b. about 1725; d. 1780. He was the son of Shikellamy, a celebrated chief of the Cayugas, who lived at Shamokin on the Susquehanna, and was called Logan from James Logan, the secretary of Pennsylvania and a firm friend of the Indians. In his early manhood he was known throughout the frontier of Virginia and Pennsylvania for his fine personal appearance, engaging qualities, and his friendship for the whites. About 1770 he removed with his family to the banks of the Ohio, where he gave way in a measure to in-

temperance. In the spring of 1774 his family were massacred, it was alleged, by a party of whites led by Captain Cresap, under the pretext of retaliation for Indian murders; but it is exceedingly doubtful whether Cresap had any connection with the transaction. Logan at once instigated a war against the scattered settlers of the far West, and for several months fearful barbarities were perpetrated upon men, women, and children. He disdained to appear among the chiefs who subsequently sued for peace, but sent by an interpreter to Lord Dunmore, the governor of Virginia, the noted speech explaining his conduct, which was first published in Jefferson's "Notes on Virginia." Its authenticity is open to much doubt, however. While intoxicated he attacked a party of friendly Indians and was killed by his relative Tod-hah-dohs in self-defense.

Logan, Benjamin, American pioneer: b. Augusta County, Va., about 1752; d. Shelby County, Ky., 11 Dec. 1802. He early crossed the Alleghanies and became a settler in Kentucky. He was an associate of Simon Kenton and Daniel Boone in the Indian fighting then constantly in progress on the frontier. During the Revolutionary War he was also active in the contests between the colonial frontiersmen and the British and their Indian allies. In 1776 he built one mile east of Stanford, Ky., on the site now called St. Asaph's Spring, the stockade known as "Logan's fort." When this fort had for weeks in 1777 been besieged by Indians, Logan made his way through the enemy's lines and traveled 150 miles to Holston where he obtained supplies and reinforcements. He participated as second in command in Colonel John Bowman's expedition against the Shawnees at Chillicothe, and led the force sent against the Indians under Simon Girty. His advance guard, through over-haste, was defeated at Blue Licks, and Logan himself did not reach the scene of battle until the succeeding day. In 1788 he commanded a force of 600 against the northwestern Indians. He was for many years a member of the Kentucky legislature; and sat also in the State constitutional conventions of 1792 and 1799. His prowess was celebrated on the frontier.

Logan, Celia. See CONNELLY, CELIA LOGAN.

Logan, Cornelius Ambrosius, American dramatist: b. Baltimore, Md., 1806; d. near Wheeling, W. Va., 1853. After a varied career as actor and manager he became a theatrical manager in Cincinnati in 1840. He made a vigorous reply to Lyman Beecher's attack upon the stage from the pulpit; and wrote several successful plays, such as: "Yankee Land" (1834); "The Way of Maine"; "A Hundred Years Hence"; a burlesque; "The Wood Dealer." He also wrote tales and poems.

Logan, George, American statesman and philanthropist; grandson of James Logan (q.v.), b. Stenton, near Philadelphia, 9 Sept. 1753; d. there, 9 April 1821. He was educated in England, subsequently studied medicine in Edinburgh, where he took the degree of M.D., and afterward returned in 1779 to America. For many years he devoted himself to agricultural pursuits, which he was one of the first in America to prosecute successfully in a scientific manner. He also served several terms in the Pennsylvania legislature. At the outbreak

LOGAN

of the French Revolution he embraced with enthusiasm its democratic doctrines, and joined Jefferson and the republican party in opposition to the federalists. In 1798, the United States being then on the brink of a rupture with the French republic, he departed for France, under the idea that he might contribute to the preservation of peace. He was well received by Tallien and Merlin, then chief of the Directory, and returned to America with the assurance of the desire of the French government to renew amicable relations with the United States. But as he had taken with him letters of introduction from Jefferson instead of passports from the state department, he was denounced by the Federalists on his return as the treasonable envoy of a faction who had undertaken to institute a correspondence with a foreign and hostile power. He was coldly received by Washington and President Adams, and in the latter part of 1798 an act, known as the "Logan act," was passed by congress, making it a high misdemeanor for a private citizen to interfere in a controversy between the United States and a foreign country as he had done. He was subsequently elected to the United States senate, of which body he remained a member 1801-7; and in 1810, urged by the same philanthropic motives which had induced him to visit France 12 years before, he went to England in the hope of preserving peace. In 1797 he published "Experiments on Gypsum" and "Rotation of Crops."

Logan, James, American colonial statesman and author: b. Lurgan, Ireland, 20 Oct. 1674; d. Stenton, near Philadelphia, Pa., 31 Oct. 1751. By his own efforts he acquired a knowledge of the chief ancient and modern languages, and in 1699, being then established in trade in Bristol, England, accepted an invitation from William Penn to accompany him to America in the capacity of secretary. In 1701, upon the return of Penn to England, he was appointed provincial secretary, and subsequently filled the offices of commissioner of property, chief justice, and president of the council, discharging in the last capacity the duties of governor of the province for two years after the demise of Governor Gordon in 1736. The latter years of his life were passed at his country-seat called Stenton, in the pursuit of literature and science. His chief work, "Experimenta et Meletemata de Plantarum Generatione" (Leyden, 1739; London, translated from the Latin by Fothergill, 1747), an expansion of a paper on the growth of maize published in the "Philosophical Transactions" for 1735, was considered an important contribution to the science of botany. He was the author of two other Latin treatises of a scientific character published in Holland, of an English translation of Cicero's "De Senectute," published in 1744 by Benjamin Franklin, and of Cato's "Distichs," the latter in verse; and he left a variety of papers on ethics and philology. The translation of Cicero was the first original one of a classical author printed in America. His library, numbering about 2,000 volumes, was, in conformity with his desire, presented to the city of Philadelphia, and is deposited in a separate department of the Philadelphia library under the name of the Loganian library. He was a member of the Society of Friends.

Logan, John, Scottish poet and Presbyterian clergyman: b. Soutra, Midlothian, Scot-

land, 1748; d. London, 28 Dec. 1788. In 1773 he was licensed as a preacher, and from his eloquence and fervor in the pulpit soon became popular. In 1786, however, owing to intemperate habits and kindred reasons, he was constrained to leave the ministry and going to London there engaged in literary work. His name is now best known in connection with that of Michael Bruce and the controversial authorship of the "Ode to the Cuckoo." That Logan is entitled to a place among the minor poets of Scotland is sufficiently attested by his exquisite lyric, "The Braes of Yarrow."

Logan, John Alexander, American soldier and politician: b. Jackson County, Ill., 9 Feb. 1826; d. Washington, D. C., 26 Dec. 1886. He studied at Shiloh College, volunteered as a private in the Mexican War, became a lieutenant in the First Illinois infantry, after the war studied law, was graduated from Louisville University in 1851, was admitted to the bar, and was elected to the Illinois legislature in 1852 and 1856. In 1858 he was elected a representative in Congress as a Douglas Democrat, in 1860 was re-elected, but resigned his seat in 1861, and on 13 Sept. was appointed colonel of the 31st Illinois infantry. He led this regiment in the attacks on Fort Henry and Fort Donelson, and was wounded at the latter. On 5 March 1862, he was made a brigadier-general of volunteers, and after commanding the 3d division of McPherson's corps (the 17th) in the northern Mississippi campaign, became major-general on 26 Nov. 1862. He fought at Port Gibson, Raymond, Jackson, and Champion Hill, commanded the centre at Vicksburg, and was appointed military governor of the town upon its capture. In November 1863 he was made commander of the Fifteenth corps, which he led until the fall of Atlanta, save for a short period when in command of the army of the Tennessee. He then returned to take part in the Lincoln presidential campaign, but rejoined his corps, continued with it till Johnston's surrender, 26 April 1865, and afterward for a time commanded the Army of the Tennessee. In 1866-9 he sat in the 40th and 41st congresses as a Republican, and was also re-elected to the 42d, but before taking his seat was chosen by the Illinois legislature to the Senate, where he served from 1871 to 1877. He began legal practice in Chicago, but on 18 March 1879 again entered the Senate. While in Congress he distinguished himself by his eloquence. He was consistently opposed to the restoration of Fitz-John Porter to the army, and in June 1880 made a four-days' speech on the Porter bill. At the Republican national convention in Chicago in June 1884, he was a candidate for nomination to the Presidency, and after Blaine's nomination was nominated Vice-President by acclamation. Shortly after the defeat of this ticket, Logan was again chosen Republican senator from Illinois. Blaine said of him: "While there have been more illustrious military leaders in the United States and more illustrious leaders in legislative halls, there has, I think, been no man in this country who has combined the two careers in so eminent a degree as General Logan." Consult the "Life" by Dawson (1887).

Logan, Mary Simmerson Cunningham, American editor and journalist: b. Petersburg, Boone County, Mo., 15 Aug. 1838. She was

LOGAN — LOGANSFORT

married to John A. Logan (q.v.) in 1855 and since his death, in 1886, has edited 'The Home Magazine,' has contributed frequently to periodicals and has been editorially associated with the 'American Journal.'

Logan, Olive, American actress, lecturer and author: b. Elmira, N. Y., 16 April 1841. She is a daughter of Cornelius Logan (q.v.) and began her career as an actress in Philadelphia in 1854. She retired from the stage in 1868; since then has been a lecturer on social topics and a contributor to newspapers and magazines. In 1872 she was married to W. W. Sikes, a journalist (d. 1883). She has published 'Chateau Frissac' (1865); 'Photographs of Paris Life' (1861); 'Women and Theatres'; and 'Before the Footlights and Behind the Scenes: a Book about the Show Business' (1870), and is the author of several plays.

Logan, Stephen Trigg, American jurist: b. in Franklin County, Ky., in 1800; d. in 1880. After studying law and for a while practising in Kentucky he removed (1832) to Springfield, Ill., and there continued in the work of his profession. He became a circuit judge in 1835; was three times (1842, 1844, 1846) elected to the Illinois legislature; and was associated as law partner with Abraham Lincoln, from 1841 to 1844. He was one of those who in 1847 framed the new constitution of Illinois; was again elected to the legislature in 1854; joined the Republican party at its formation, and was a delegate to its national convention in Chicago in 1860, at which Lincoln was nominated for the presidency. His reputation as a lawyer was very high among the members of his profession, and for eminence at the bar he left a still honored name.

Logan, Sir William Edmond, Canadian geologist: b. Montreal 20 April 1798; d. Castle Malgwin, Cardiganshire, Wales, 22 June 1875. He was educated chiefly in Edinburgh; was for a time a clerk in London, and afterward became manager of a copper-smelting works in Swansea. While there he devoted himself to the study of geology. In 1840 he went to Canada, and he was the chief of the Geological Survey of that country 1842-70. His writings appeared in the annual reports of the Canadian Survey; in the Proceedings of the British Association, the Geological Society, etc. He was knighted in 1856; was a knight of the Legion of Honor, and recipient of the Wollaston medal from the London Geological Society. He published 'Geology of Canada' (1863). Consult 'Life,' by Harrington (1883).

Logan, Ohio, village, county-seat of Hocking County; on the Hocking River, and on the Columbus, Hocking & Toledo railroad; about 45 miles southeast of Columbus. It is situated in the natural gas belt, and in the vicinity of some good farm lands. Nearby is found clay suitable for pottery and bricks. Its chief manufactures are flour, furniture, brick for paving and building, pottery, foundry products, and machinery. The village owns and operates the waterworks. The public library has nearly 3,000 volumes. Pop. (1900) 3,480.

Logan, Utah, city, county-seat of Cache County; on Logan River, and on the Oregon

Short Line railroad; about 70 miles north of Salt Lake City. It was settled in 1859 and incorporated in 1866. It is located in an agricultural region with valuable mineral deposits in the vicinity. The chief industrial establishments are knitting-mills, lumber-mills, a brewery, a beet-sugar factory, and flour-mills. Some of the educational institutions are the Brigham Young College, opened in 1878 under the auspices of the Latter Day Saints, New Jersey Academy, under the auspices of Presbyterians, and the State Agriculture College. The water-works are owned and operated by the city. The city government is according to the act of 1868, providing for the general government of the cities of the State. Pop. (1900) 5,451.

Logan, Mount, one of the highest peaks of the Rocky Mountain system, in the southwestern part of the district of Yukon in Canada. Its height is 19,500 feet. The report of the United States Geological Survey of 1898 ranks this peak as second in height in North America; Mount McKinley (q.v.) being first.

Logania'cea, an order of trees, shrubs and herbaceous plants, with opposite entire leaves, and usually with stipules, which adhere to the footstalks or form sheaths. A few species of this order occur in Australia and in the temperate parts of North America; the rest are all tropical or sub-tropical. No order of plants is more strongly characterized by poisonous properties. It includes the genus *Strychnos* and the plant which yields the poison curari (q.v.).

Logansport, Ind., city, county-seat of Cass County; at the junction of the Wabash and Eel rivers, and on the Wabash, the Pittsburg, C. & St. L., the Toledo & L., and the Vandalia R.R.'s; about 70 miles north of Indianapolis. It is situated in a fertile agricultural section in which the chief farm products are wheat, corn, and vegetables. It is the trade centre for a section which has a population of about 120,000. It has excellent water-power, and natural gas. The chief manufacturing establishments are car-truck and automobile factories, motor-works, basket and broom factories, flour and lumber-mills, wagon and carriage factories, lime and cement works. The railroad shops employ about 1,000 men, the Dorner Truck Foundry and the Western Motor Company employ about 300 each.

The educational institutions are Holy Angels' Academy (R. C.), Logansport Business College, a high school, public elementary schools, Roman Catholic and Lutheran parish schools. There are 17 churches, Saint Joseph's Hospital, and the Northern Indiana Hospital for the Insane. There is a farm of about 300 acres connected with the Insane Hospital. The city has a government building, a Carnegie library, county court-house, and a large number of fine residences. There are five banks with a combined capital of \$750,000. Several bridges connect the city with places across the Wabash and Eel rivers. The city owns and operates the electric-light plant and the waterworks. The government is vested in a mayor, who holds office four years, and a council of 10 members. The council elects the board of education and all the administrative officials except the police commissioners, who are appointed by the Governor

LOGARITHMIC CURVE—LOGIC

according to a State law for municipalities. Pop. (1890) 13,328; (1900) 16,204.

A. R. KEESLING,
Editor of 'Daily Journal.'

Logarithmic Curve, in mathematics, a curve discovered by Gregory; it is the locus of a point such that its distance from a line is in a constant ratio to the logarithm of its distance from another line at right angles to the first. Its equation is $y = a^x$. The logarithmic or equiangular spiral is a curve which cuts all the lines drawn from a certain point at the same angle. Its equation is $r = a\theta$. Professor Tait has shown that when a pendulum swings in a resisting medium, or whenever a body moves in a straight line under the influence of a force which varies as the distance of the body from a fixed point, and when at the same time there is a resistance to its motion which is proportional to its velocity, the motion of the body is the same as the projection on a straight line of uniform motion in an equiangular spiral.

Log'arithms. The common logarithm of a number is the index of the power to which 10 must be raised to be equal to the number. Thus $10^3 = 1,000$, so that the logarithm of 1,000 (usually written log. 1,000) is 3. Now $10^0 = 10$, $10^{-1} = 100$, $10^0 = 1,000$, $10^{-2} = 1,000,000$, and it is well known that $10^{-3} = 1$, $10^{-4} = 0.1$, $10^{-5} = 0.01$, etc., thus:

Log. 0.001 = -3	Log. 10 = 1
Log. 0.01 = -2	Log. 100 = 2
Log. 0.1 = -1	Log. 1,000 = 3
Log. 1 = 0	Log. 10,000 = 4

It is evident that the logarithm of any number greater than 1 and less than 10 is fractional; the logarithm of any number greater than 10 and less than 100 is greater than 1 and less than 2. Again, the logarithm of any number less than 1 is negative. The logarithms of numbers have been calculated by Napier, Briggs, Mercator, Newton, Leibnitz, Halley, Euler, L'Huillier, Vlacq, Sherwin, Gardner, Hutton, Taylor, Callet, and others. Of works giving tables of logarithms we may mention those to which the names of Hutton, Callet, and Vega are respectively attached. Chambers' Mathematical Tables is a useful little treatise; it gives logarithms of numbers to seven places of decimals. Suppose we wish to know the logarithm of the number 18.1. In a book of tables we only find the fractional part of the logarithm, it is .257679. Now 18.1 is greater than 10 and less than 100, so that its logarithm is greater than 1 and less than 2; hence log. 18.1 = 1.257679. To give examples:

Log. 18100 = 4.257679	Log. 1.81 = 0.257679
Log. 1810 = 3.257679	Log. 0.181 = 1.257679
Log. 181 = 2.257679	Log. 0.0181 = 2.257679
Log. 18.1 = 1.257679	Log. 0.00181 = 3.257679

.257679 means $-3 + 0.257679$. For a full explanation of the finding of logarithms and natural numbers by the tables see treatises on trigonometry, etc. The integral part of a logarithm is called its characteristic, the fractional part its mantissa. Logarithms make arithmetical computations more easy, for by means of a table of them the operations of multiplication, division, involution or the finding of powers, and evolution or the finding of roots, are changed to those of addition, subtraction, multiplication, and division respectively. For instance, if x and y are the logarithms of any two numbers, the numbers are 10^x and 10^y ; now the product of these

numbers is 10^{x+y} , so that the logarithm of the product of two numbers is the sum of the logarithms of the numbers. Again, the quotient of the numbers is 10^{x-y} ; so that the logarithm of the quotient of two numbers is the difference of the logarithms of the numbers. Again, 10^x raised to the n th power is 10^{nx} ; so that the logarithm of the n th power of a number is n times the logarithm of the number. Again, the n th root of 10^x is $10^{\frac{x}{n}}$; so that the logarithm of the n th root of a number is $\frac{1}{n}$ th of the logarithm of the number. Hitherto we have spoken of common logarithms, which were invented by Briggs; their base, as it is called, is 10. Now logarithms were first used by Napier of Merchiston (see NAPIER, JOHN), and he employed a base which is smaller than 10, it is the number 2.7182818..., or the sum of the infinite series $2+\frac{1}{4}+\frac{1}{8}+\frac{1}{16}+\dots$, etc. This base is denoted by e in mathematical treatises, and the Napierian logarithm of any number, say 7, is $\log_e 7$, to distinguish it from $\log 7$, which is the common logarithm, whose base is 10. The common logarithm of a number is found from the Napierian by multiplying by 0.43429448. Napierian logarithms are of great importance in mathematics.

Log'cock, a local name for either of two birds: (1) the pileated woodpecker (see WOODPECKER); (2) the woodcock (q.v.).

Log'gerhead Shrike. See TURTLE.

Loggerhead Turtle. See HAWKSBILL.

Loggia, lōj'a, a word used in Italian architecture with several significations. It was applied to a hall open on two or more sides, where there were pillars to support the roof. Such are the Loggia de' Banchi in Genoa, and the Loggia de' Lanzi in Florence. It is also applied to an open colonnade along the side of a building. The name loggia is also given to the large ornamental window consisting of several parts, which is often seen in old Venetian palaces; and lastly, it is used to designate a small airy hall, usually open on all sides, constructed on the roof of an edifice. See also ARCHITECTURE.

Log'ging, a name given by lumbermen to the practice of rolling logs from whence they are cut, or drawing them on sleds or wagons, to the stream by which they are transported to the mill. In some places logs are thus moved from one point to another by means of flumes and waterways.

Logic, an art which treats of reasoning, together with the operations of the mind subsidiary to reasoning. Its chief end is to ascertain the principles on which all valid reasoning depends, and which may therefore be applied as tests of the legitimacy of every conclusion that is drawn from premises. Thus Whately defines logic as "the science and art of reasoning," and Whewell says that "by logic has generally been meant a system which teaches us to arrange our reasonings that their truth or falsehood shall be evident in their form." Hamilton defines it as "the science of the laws of thought as thought." Some logicians would extend the sphere of logic further than is consistent with any of the definitions just given, and make it coextensive with the science and theory of evidence in the most general sense of that term; but we shall be following the most general

LOGIC

usage if we confine it to the study and estimation of such evidence as depends for its sufficiency more or less immediately on some admitted truth which is at least equally general in its nature with that which it is held to prove.

Divisions.—Logic has been divided, according to different principles, into objective and subjective (*Logica systematica* and *Logica habitualis*); into abstract or general and concrete or special (*Logica docens* and *Logica utens*); into pure and modified; and into deductive and inductive. The first of these divisions looks at logic, on the one hand, as a systematized body of truths on the subject of which it treats, and, on the other hand, as the knowledge of these truths which is possessed by an individual, and the ability which that individual displays in applying them. The second division, into abstract and concrete, considers logic in the first case apart from any of its particular applications, and in the second case as applied to some particular art or science. The division into pure and modified logic looks at that science first in its naked theory, and secondly as modified in its application to the search after truth by the mental constitution of man generally or particular individuals; or, in other words, pure logic treats of the laws of correct reasoning and what is connected therewith, and modified logic treats of those circumstances that are likely to lead men into error in reasoning.

Deductive Logic.—As we have already said, it is the function of logic to treat not only of reasoning, but also of the operations of the understanding subsidiary to reasoning. Reasonings come under the examination of logic only as they are expressed in words; thus only can they appear in such a form that their truth or falsehood will be instantly evident, according to the requirements of Whewell's definition of the science. As expressed in words reasonings are composed of judgments or propositions, and judgments are composed of terms, general or particular. Naming and judging are therefore two operations of the understanding, and names and propositions two mental products which, as subsidiary to reasoning, belong to the province of logic.

Laws of Thought.—But before saying anything on these subsidiary operations it is necessary to state the three axioms or fundamental laws of thought which regulate the understanding in all its operations whether of naming, judging, or reasoning, and which are in themselves self-evident. These are, 1, the law of identity; 2, the law of contradiction or difference; and 3, the law of excluded middle. The law of identity expresses the fact that everything is the same as itself: its formula is A is A. The law of contradiction or difference expresses the fact that nothing can be the same as its contradictory: its formula is A is not Not-A. The law of excluded middle expresses the fact that one or the other of two contradictory propositions must be true: It asserts the truth of the formula A is either B or not B. Applying these laws to naming then, we can affirm that every name must be the same as itself; that no name can be thought as expressing contradictory attributes; that no name, for example, is thinkable as expressing at once the attributes of rationality and irrationality; and that of every name we can assert that any attribute either is or

is not expressed by it. To these laws some writers add the law of reason and consequent, expressed by the formula, Infer nothing without a reason.

Names or Terms.—It would be impossible without extending the length of this article disproportionately to go very minutely into the theory of naming. It is enough to mention that names are applied to persons or things, either in virtue of certain attributes which they possess, or merely in order to distinguish one individual from another. The former have been aptly called connotative, because they connote (mark together) or express the attributes which constitute their meaning, and they may be applicable either to single individuals (as God, the sun), or to numbers of individuals (as man, horse). The latter are called non-connotative, and are applicable only to single individuals, or if applied to more than one individual, are not applied in virtue of any qualities that these may happen to possess in common. The attributes expressed by a name are called its connotation, and the individuals to which it is applicable its denotation. Some writers, instead of the connotation and denotation of a name, speak of the comprehension and extension of a concept, which is the sum of the qualities expressed by a name. The comprehension of a concept is thus these qualities considered in themselves, and the extension the aggregate of individuals in which these qualities are found to exist.

Judgments.—Judgments or propositions are the forms in which our beliefs are expressed in language. In them we either affirm or deny something to be true of something else. The term expressing that of which the assertion is made is called the subject; that which expresses what is denied or affirmed of the other is called the predicate. Sometimes there is a separate word or phrase to connect the subject and predicate, and to show whether the latter is affirmed or denied of the former. This is called the copula ('is' or 'is not' or 'are' or 'are not').

Distribution.—The words all, some, etc., showing whether the subject of a proposition is distributed or not, are said to indicate the *quantity* of the proposition. Sir W. Hamilton advanced the theory that in every proposition the predicate should have a sign of quantity as well as the subject, so that every proposition should be a perfect equation. This is what is called the doctrine of the quantification of the predicate, but it has not been generally received into the expositions of deductive logic, and has been positively objected to by some logicians as involving a misrepresentation of the nature of a proposition. Propositions the subject of which is distributed are called *universal* or *singular*, according as the subject is applicable to more than one or to only one individual; those of which it is undistributed, *particular*. When there is no sign to indicate whether the subject is distributed or not, the proposition is called *indefinite*, in place of which Sir William Hamilton introduced the term *predesignate*, applying the term *predesignate* to those in which the quantity was overtly expressed.

Quality.—As judgments are said to differ in quantity according to the distribution or non-distribution of their subject, so they are said to differ in *quality* according as they are affirmative or negative; and with reference to both

LOGIC

quality and quantity they are divided into four classes—universal (or singular) affirmative, represented by the vowel A; universal negative, represented by E; particular affirmative, represented by I; and particular negative, represented by O. Examples of the four are: All men are liable to err; No man is the exact counterpart of another; Some men are wise; Some men are not wise.

Conditional Judgments.—Hitherto we have only treated of what are called categorical propositions, that is, those in which something is directly affirmed or denied of the subject; but there is another class in which the predication is not direct. Of such propositions there are three kinds, hypothetical, disjunctive, and hypothetico-disjunctive or dilemmatic. *Hypothetical* propositions are such as have a condition attached to the predicate, as, If A is B, C is D, or if A is B, it is C. The condition is called the *antecedent*, and the proposition whose truth depends upon the condition is called the *consequent*. *Disjunctive* propositions are such as in effect, though not in form, affirm the truth of one of two or more propositions, such as, Either A is B, or C is D, or again, A is either B or C or D, the first of which is equivalent to, One of the two propositions A is B, C is D is true; and the second to, One of the propositions, A is B, A is C, A is D, is true. Such propositions are often treated by logicians as if the alternative excluded the possibility of more than one of the propositions being true. The first of the examples given would, according to this rule, be considered as equivalent to, One, and only one, of the propositions A is B, C is D is true; and the second, One, and only one, of the propositions A is B, A is C, A is D is true. But this is quite an uncalled for limitation of the meaning of the phrase disjunctive proposition, and leaves one form of proposition without a name; for judgments in which we assert that at least one of two or more alternatives is true, are often made without the intention of excluding the possibility of more than one being true. It might be said, for example, of a man who had expended great sums of money in projects of questionable utility, that he must either be very wealthy or very foolish, without meaning to state that he could not be both very wealthy and very foolish. Indeed, it would be more proper to regard the latter sense as the true meaning of a disjunctive proposition, inasmuch as that expresses all that is necessarily implied in a proposition of that form. The last kind of indirect proposition, the *hypothetico-disjunctive* or *dilemmatic* is a compound of both the other two, in some such form as, If A is B, C is either D or E. As a hypothetical proposition affirms (or denies) some predicate of some subject conditionally, a hypothetico-disjunctive proposition affirms (or denies) the truth of one or other of two or more propositions conditionally.

Immediate Inference.—Before we pass from judgments to reasonings, or the doctrine of syllogisms, we have to consider four methods of treating propositions, so as to derive other propositions, the truth or falsity of which is implied in the original propositions. These methods are called processes of immediate inference.

1. Contraposition.—The first of these processes is called *contraposition*. Thus, the prop-

osition, All men are mortal, becomes by contraposition, No man is immortal.

2. Subalternation.—The second process is through the relation of *subalternation*. This relation subsists between universal propositions, whether affirmative or negative, and their corresponding particulars, or between A and I, and between E and O, when the terms of the propositions are otherwise the same. A and E are called *subalternants* with reference to I and O respectively, and I and O are called with reference to them *subalternates*.

3. Opposition.—The third process of immediate inference is of somewhat more importance. It depends upon the doctrine of *opposition*. The laws of immediate inference bearing upon propositions standing to one another in the relation of opposition are the following: 1. Of two contradictory propositions one must be true, and the other false. If it is true that All A's are B, it must be false that Some A's are not B; if it is false that Some A's are B, it must be true that No A is B. 2. Two contrary propositions may both be false, but they cannot both be true. If it is false that All A's are B, it may nevertheless be equally false that No A is B; but if it is true that All A's are B, it must be false that No A is B; and if it is true that No A is B, it must be false that All A's are B. 3. Two sub-contrary proposition may both be true, but they cannot both be false. If it is true that Some A's are B, it may be none the less true that Some A's are not B; but if it is false that Some A's are B, it cannot be false that Some A's are not B.

4. Conversion.—The last process of immediate inference is also important, especially on account of the part it plays in the theory of the syllogism as usually expounded. In every kind of conversion the proposition in its original form is called the *convertend*, and the proposition into which it is changed the *conversa* or *conversc*. The law of conversion is that no term must be distributed in the converse which was not distributed in the convertend. Thus the converse of All A=B is, All B=A. No A=B by conversion becomes No B=A, Some A=B is converted into Some B=A, etc.

Ratiocination.—We now come to that which forms the main subject of deductive logic, the theory of ratiocination, or the syllogism. All deductive reasonings, or reasonings from generals to particulars, must necessarily be capable of being stated in the form of a syllogism, and on being so stated their validity will be evident from their form. A *syllogism* consists of three propositions, two of which, called collectively the *antecedent*, and separately the *premises*, state the grounds of the inference deduced; while the third, called the *consequent* or *conclusion*, states what that inference is. Every syllogism consists of three terms, each of which occurs twice. Of these one occurs twice in the antecedent, once in each premise, and is called the *middle term*. The other two occur once in the antecedent, and once in the consequent. That which is the subject of the consequent is called the *minor term*, and that which is the predicate the *major term*. Both together are sometimes called the *extremes*. The premise containing the major term is called the *major premise* (by Sir W. Hamilton the *sumption*). That containing the minor term is called the *minor premise* (by Sir

LOGIC

W. Hamilton the *subsumption*). It is a matter of no consequence to the validity of a syllogism in what order the propositions are given; but in logical treatises the usual order is 1st, major premise, 2d, minor premise, 3d, conclusion; and all logical formulas referring to the syllogism are based on the assumption that its parts are so stated.

Figure.—The syllogism may appear in four different forms, called *figures*, according to the position of the middle term, which may be subject in the major premise and predicate in the minor, predicate in both premises, subject in both premises, or predicate in major and subject in minor. These figures are known as first, second, third, and fourth, and are usually represented by the following scheme, in which P (predicate of conclusion) stands for the major term, S (subject of conclusion) for the minor, and M for the middle:

	Fig. 1	Fig. 2	Fig. 3	Fig. 4
Major premise	M P	P M	M P	P M
Minor premise	S M	S M	M S	M S
Conclusion.....	S P	S P	S P	S P

The Ground of Validity of Syllogistic Reasoning.—Logicians commonly base the validity of the syllogistic process upon some form of the canon, called the *Dictum de omni et nullo*, which in its Latin form reads thus—*Quicquid de omni valet, valet etiam de quibusdam et singulis; quicquid de nullo valet, valet nec de quibusdam nec de singulis;* which may be interpreted in English thus: “Whatever is true of a whole class, is true of what is included in that class.”

Mood: Syllogistic Rules.—We have already seen that what determines the figure of a syllogism is the position of the middle term. Another division of syllogisms is determined by the quantity and quality of the propositions of which they are composed. If the four propositions A E I O be taken three together in different order there will be sixty-four sets, and if all these sets made legitimate syllogisms there would be sixty-four moods irrespective of figure. But if we test these sets by rules deduced from the syllogistic canon, we shall find that the great majority of them cannot make legitimate syllogisms. These rules are six in number: 1. In every syllogism there must be three, and only three terms. If this rule were overtly violated the pretended reasoning would not even have the form of a syllogism. 2. The middle term must be distributed in one of the premises. 3. Neither the minor term nor the major must be distributed in the conclusion, if it was undistributed in the premises. The first part of this rule implies that if one of the premises is particular the conclusion must be particular; and the second part of the rule, taken in conjunction with the second rule, implies that from two particular premises no conclusion can be drawn. 4. If both premises are affirmative, the conclusion must be affirmative. 5. If either of the premises is negative, the conclusion must be negative. 6. From two negative premises no conclusion can be drawn.

Let us now apply these rules to ascertain the number of logical moods. Two of them, the sixth and the corollary deduced from the second and third, apply to the premises exclusively, in such a manner as to serve as tests of the possibility of the various pairs of propositions

entering into legitimate syllogisms as premises. The number of different pairs of propositions taken in different order is sixteen. They are AA, AE, AI, AO, EA, EE, EI, EO, IA, IE, II, IO, OA, OE, OI, OO. Three of these, II, IO, and OI, are excluded by the corollary to the second and third rules affirming that from two particular premises no conclusion can be drawn; three, EE, EO, and OE, are excluded by the sixth rule forbidding two negative premises; and one, OO, is excluded by both. If we closely examine the pair IE we shall find that it also must be excluded, for it follows from the first corollary to the third rule, and from the fifth rule, that any conclusion derived from these premises must be both particular and negative, that is O. But in such a conclusion the predicate would be distributed, whereas it could not have been distributed in the major premise I, as both terms of it are particular. A syllogism with the premises IE must therefore be a violation of the third rule. There thus remain only eight pairs of premises capable of entering into a valid syllogism, namely AA, AE, AI, AO, EA, EI, IA, and OA. Three of these being universal both in the major and minor, AA, AE, and EA, may give either universal or particular conclusions. The conclusion of the others must be particular. There are thus eleven different sequences of propositions which yield valid syllogisms, AAA, AAI, AEE, AEO, EAE, EAO, AII, AOO, EIO, IAI, and OAO, and if all these could occur in each of the figures there would be forty-four syllogistic moods; but this number is limited by the special rules applicable to the different figures and we must state these rules before we can see what are the valid moods for each.

The rules for the First Figure are three: 1. The minor premise must be affirmative. 2. The major premise must be universal. 3. The quality of the major premise determines the quality of the conclusion, and the quantity of the minor the quantity of the conclusion.

We will again demonstrate one of these rules, say the second, for the sake of illustration. It will be remembered that the formula of the first figure is MP, SM, SP. Now if the major premise is not universal, its subject, the middle term, is not distributed; and as the minor premise by the first of our special rules must be affirmative, its predicate, also the middle term, cannot be distributed. The middle term is thus distributed in neither case, and the second general rule is violated. If we apply our special rules then to the eleven model forms we shall find that only four of them, AAA, EAE, AII, and EIO, can be exhibited in the first figure. The two, AAI and EAO, would also yield legitimate syllogisms, but as they infer a particular conclusion when a universal one, in accordance with the rule that the quantity of the minor premise determines that of the conclusion, is warranted, they are not used; and the same applies to two cases in the second and one in the fourth figure.

The rules for the Second Figure are also three: 1. One of the premises must be negative. 2. The conclusion must be negative. 3. The major premise must be universal.

Applying these rules to our eleven model forms we again obtain four valid moods, AEE, EAE, AOO, EIO. AEO and EAO are the two which are rejected as yielding a particular conclusion when a universal one is warranted.

LOGIC

The rules for the Third Figure are two: 1. The minor premise must be affirmative. 2. The conclusion must be particular.

These two rules admit of six valid moods, namely, AAI, EAO, AII, EIO, IAI, and OAO.

The rules for the Fourth Figure have been variously stated, but the three following may be given as the most comprehensive of those that have been devised for it: 1. If the major premise is affirmative the minor premise must be universal. 2. If one premise is negative the major premise must be universal. 3. If the minor premise is affirmative the conclusion must be particular.

These special rules yield the five moods, AAI, AEE, EAO, EIO, and IAI. AEO is rejected on account of its having a particular conclusion when a universal one is warranted.

We now see that there are in all nineteen syllogistic moods, and in one or other of these every categorical deductive reasoning must be expressed before its validity can be tested. The difficulty of retaining these moods in the memory has led various logicians to embody them in mnemonic lines. The most ingenious are those invented in barbaric Latin for the first three figures by Petrus Hispanus, who filled the papal chair with the title of Pope John XX. or XXI. in 1276-7. These lines not only represent by the ordinary vowels the syllogistic moods, but in the second and third figures also indicate by certain consonants the method by which they are to be reduced to syllogisms of the first figure. The mnemonics for the fourth figure are wanting in the lines of Hispanus, because that figure was not recognized by the earliest logicians (as it is still indeed condemned by many on account of its awkward and irregular mode of inference), but they were afterward added in a new line. In their complete form these mnemonics stand thus:—

I. bArBArA, cElArEnt, primæ, dArII,
fErIOque:
II. cEsArE, cAmEstrEs, fEstInO, bArOcO,
secundæ:
III. tertia dArAptI, dIsAmIs, dAtIsI,
fElApOn,
fErIsO, bOcArD O, habet: quarta insuper
addit

IV. brAmAntIp, cAmEnEs, dImArIs, fEs-
ApO, rEsIsOn.

The vowels printed in capitals, it will be seen, show the moods of each figure; and for the consonants, the initial one shows that the syllogisms in the three last figures must be reduced to the one beginning with the same consonant in the first; *s* indicates that the previous proposition must be simply converted; *p* that it must be converted *per accidens*, that is, the quantity of the proposition must be changed; *m* that the premises may be transposed (*metathesis* or *mutatio*); and *r* following a vowel indicates that the process to be resorted to is that called *reductio ad impossibile*.

Fallacies.—A section on fallacies or invalid reasonings forms the usual supplement to an exposition of the theory of deductive logic. As a complete statement of the principles of ratiocination must contain tests of the validity of all valid deductive reasonings, every fallacy or invalid reasoning must consist in a violation of one or other of these principles, that is, in a violation of some one or more of the six general laws applicable to the categorical syllogism or of the

rules given for regulating the modes of inference in conditional syllogisms. A violation of the first law of the syllogism, that which requires that there shall be only three terms in it, can happen in such a manner as to leave the form of a true syllogism, only when the same middle term is used in different senses in the two premises, that is, when the middle term is ambiguous in meaning—a very common source of fallacy. The violation of the second rule as to the distribution of the middle term in one of the premises is called the fallacy of *Undistributed Middle*. The violation of the third, which says that no term must be distributed in the conclusion if it was not distributed in the premises, is called an *Illicit Process*. If it is the minor term in which the fallacy arises it is called the *Illicit Process of the Minor*; if it is the major term, the fallacy is called the *Illicit Process of the Major*. The fallacies of undistributed middle and illicit process are called *Fallacies of Quantity*, violations of the remaining syllogistic laws (4th, 5th, and 6th) are called *Fallacies of Quality*. For these there are no special names, nor for the violations of the laws relating to conditional syllogisms. These are all the fallacies belonging to the form of ratiocination, which is all that deductive logic has properly anything to do with. See **FALLACY**.

INDUCTIVE LOGIC. Definition of Induction.—Having thus completed our summary of the received exposition of deductive logic we now pass to the other section of the science, to which the name of Inductive Logic is given; and in treating of it we will confine ourselves to the views of J. S. Mill, the writer whom we have already mentioned as the most systematic expositor of that part of logical science. Induction is shortly defined by him as "generalization from experience." At another place he states more minutely that "it consists in inferring from some individual instances in which a phenomenon is observed to occur, that it occurs in all instances of a certain class; namely, in all which resemble the former, in what are regarded as the material circumstances." Again, Induction is, "without doubt, a process of real inference. The conclusion in an induction embraces more than is contained in the premises. . . . A principle ascertained by experience is more than a mere summing up of what has been specifically observed in the individual cases which have been examined: it is a generalization grounded on those cases, and expressive of our belief that what we there found true is true in an indefinite number of cases which we have not examined, and are never likely to examine."

Inductive Canons.—We may now proceed at once to state the rules which Mill gives for generalizing from experience, the rules to which he gives the name of *Inductive Canons*.

I. The first he calls the Method of Agreement, which he enunciates thus: "If two or more instances of the phenomenon under investigation have only one circumstance in common, the circumstance in which alone all the instances agree is the cause (or effect) of the given phenomenon." He gives the following as the axiom upon which it depends: "Whatever circumstance can be excluded without prejudice to the phenomenon, or can be absent notwithstanding its presence, is not connected with it in the way of causation. The casual circumstances being thus eliminated, if only one remains, that one is the

LOGIC

cause which we are in search of: if more than one, they either are, or contain among them, the cause." The canon is exhibited in the formula $ABC, abc; ADE, ade; AFG, afg$; where a may be taken to represent the phenomenon under investigation, and A therefore, in accordance with the canon just stated, will be the cause of a , as it is the only circumstance in which all the cases in which a occurs agree. To illustrate these canons by concrete examples in such a manner as to give anything like a satisfactory idea of their application in scientific inquiry would occupy far too much of our space, and we must therefore refer the reader who is desirous of seeing this done to Mill's own work (*System of Logic*, Book III. ch. ix.). We may, nevertheless, mention as a trifling example of this method, that it is by it that we know that every plant reproduces its own kind. Our knowledge of this fact is an inference from the uniform observation that all plants of a particular species agree in having proceeded from some member of that species, whether by seed, bud, slip, or any other means. This method is of very wide application, but it must be mentioned that it labors under two defects, one of which even invalidates its theoretic accuracy. The first defect consists merely in the difficulty of having the conditions of the method fully satisfied, that is, the difficulty of ascertaining that the cases investigated do agree only in one particular. The other defect arises from the plurality of causes, or from the fact to which attention has already been drawn, that different causes may produce the same effect. This circumstance renders the axiom on which the canon is said to depend false, for although a circumstance which was present, in which a phenomenon occurred, may be absent in another case, in which the same phenomenon occurs, this does not prove that the circumstance in question did not in the first instance produce the phenomenon. It may have been the cause in one case, and something else in another.

II. The second canon is called the Method of Difference, and according to Mill depends on the axioms, "Whatever antecedent cannot be excluded without preventing the phenomenon is the cause, or a condition, of that phenomenon. Whatever consequent can be excluded, with no other difference in the antecedents than the absence of a particular one, is the effect of that one." The canon itself is this: "If an instance in which the phenomenon under investigation occurs, and an instance in which it does not occur, have every circumstance in common save one, that one occurring only in the former, the circumstance in which alone the two instances differ is the effect, or the cause, or a necessary part of the cause of the phenomenon." The formula of the canon (the same notation being used) is $ABC, abc : BC, bc$. A must be the cause of a . This is by far the most important of the inductive canons, both on account of the extent of its application, and also from its being free to a great extent from the practical difficulties besetting the application of the first method, and altogether free from objection as to its theoretical validity. If the only things that could have produced a are ABC , and BC alone are not sufficient to produce it, it follows inevitably that A is at least an indispensable part of its cause. Examples of inference in accordance with this canon are constantly occurring. We

may find at least two in the illustration we have already used of the ball on a level surface acted upon by an outward force. It is by the method of difference we know that the motion of the ball across the surface is due to the impact of the other solid body, for before that impact the ball was stationary, but immediately after it began to move, although (as we have supposed) no other change took place in the circumstances. It is also by the method of difference that we know that in the second instance, when the ball was placed upon a rough surface, and acted upon by the same force as in the first, its stopping before it reached the point it had reached in the first instance is due to the roughness of the surface, for that is the only circumstance in which the cases differ.

III. The third of Mill's canons of inductive logic is an attempt to combine the first two, with the object of helping to remove the uncertainty which belongs to the first. It is called the Indirect Method of Difference, or the Joint Method of Agreement and Difference, and is stated thus: "If two or more instances in which the phenomenon occurs have only one circumstance in common, while two or more instances in which it does not occur have nothing in common save the absence of that circumstance, the circumstance in which alone the two sets of instances differ is the effect, or cause, or a necessary part of the cause of the phenomenon." Its formula is $ABC, abc; ADE, ade; AFG, afg : HBC, hbc; IDE, ide; KFG, kfg$. We may again return to our illustration from vegetable reproduction for an example of this method. If, besides examining the cases in which plants of a certain species are produced, we examine those in which they are not produced, but, we will suppose, some other plants closely resembling them are produced, and find that the circumstances attending the production of these latter differ from those attending the production of the former only in respect of the origin of the seed, bud, slip, or whatever else it may be from which they respectively proceeded, we shall have a case of the joint method of agreement and difference; and our conclusion in the former case will be greatly strengthened. This method is, however, no more theoretically rigorous than the first, for even although we exhaust in the negative set of instances all the antecedents that were found in the positive set except one, yet we can never be sure that that one is the cause as long as the negative instances, besides excluding the one that was found constant in the positive set, include some new circumstance or circumstances besides those that were found in combination with A in the positive set, for these new circumstances may have been the very causes why the phenomenon under investigation did not occur. In ABC, abc , B may have been the cause of a , and in HBC, hbc , H may have been the circumstance that counteracted the operation of B , so that a did not appear: in ADE, ade , D may have been the cause of a , and may have been counteracted in IDE, ide , by I .

IV. The fourth inductive canon is called the Method of Residues, and, like the method of difference, is based upon the principle of a complete elimination of all circumstances not connected by way of causation with the phenomenon under investigation. It is this: "Subduct from any phenomenon such part as is known by previous inductions to be the effect of certain

LOGOMANIA — LOGOS

antecedents, and the residue of the phenomenon is the effect of the remaining antecedents.' It is by an application of this method that when we know the weight of a vessel and its contents, and also the weight of the vessel alone, we can infer the weight of its contents. This is manifestly equally rigorous in its principle with the method of difference.

V. The last inductive canon is applicable to those cases in which we cannot obtain a case of the method of difference, owing to the impossibility of removing the phenomenon under investigation. Thus we cannot entirely remove heat from a body, and therefore cannot observe the effect of heat by examining some body first without and then with heat. We cannot remove the sun from the solar system, and therefore cannot tell by actual experiment what effect its absence would have. In these circumstances we resort to the Method of Concomitant Variations, which depends on the axiom, "Anything on whose modifications modifications of an effect are invariably consequent must be the cause (or connected with the cause) of that effect." The canon itself is enunciated thus: "Whatever phenomenon varies in any manner whenever another varies in some particular manner is either a cause or an effect of that phenomenon, or is connected with it through some fact of causation." Although we have no opportunity of observing any body absolutely deprived of heat, we can observe the same body at different temperatures. It is in this way that we discover that heat has the effect of expanding bodies, for with no other change than an increase of temperature we see that mercury expands.

Consult Whately's 'Logic'; some articles on the subject in Sir W. Hamilton's 'Discussions' (second edition, 1853); 'Lectures on Logic' by the same author (1860); Thomson's 'Outlines of the Laws of Thought'; Ueberweg's 'System der Logik und Geschichte der Logischen Lehren' (5th ed., 1882); De Morgan's 'Formal Logic' (in which mathematical principles are applied); Boole's 'Mathematical Analysis of Logic'; Keynes's 'Formal Logic' (1884); Bosanquet's 'Logic' (1888); Sigwart's 'Logik' (2d ed., 1889); Wundt's 'Logik' (2d ed., 1893); Erdmann's 'Logik' (1892); Lotze's 'Grundzüge der Logik'; and Minto's 'Logic' (1893). On inductive logic see Sir John Herschel's 'Preliminary Discourse on the Study of Natural Philosophy' (London, 1831); Whewell's 'Philosophy of the Inductive Sciences' (1840); and especially Mill's 'System of Logic' (1843).

Logoma'nia (Greek *λόγος*, word; *μανία*, madness), violent disturbance of speech; utter confusion of words, often with great loquacity, and with dissociation of language and ideas; the extreme type of aphasia (q.v.).

Log'o's (Greek *λόγος*, from *λέγειν*, to speak), word, language, speech in general. Language being peculiar to man as a reasonable being, and speech presupposing thought, *logos* signifies reason, the faculty of thinking in general. Thus *logos* has the meaning both of thought and utterance. In Christian theology this term as used in certain passages of the Scriptures, has been the source of continual disputes ever since the 3d century of our era. The passage in the Bible which gives rise to this discussion is the opening of the Gospel of St. John: "In the beginning was the Word, and the Word was with

God, and the Word was God. The same was in the beginning with God. All things were made by him, and without him was not anything made that was made," etc. In the Greek text the expression here translated "Word" is *logos*. What is here to be understood by *logos*, what is its essential character, whether it is a person of the Deity or not, the creative intellect of God, or the Son, through whom he created, or the divine truth which was to be revealed, etc., this is not the proper place to examine, nor will our limits permit us even to enumerate the different opinions which have been entertained on this interesting point of Christian metaphysics. We can refer the reader to no better source of information than Neander's 'General History of Christianity and the Church.' The generally received doctrine of the *logos* makes it a person and not a mere name, and maintains that the Word is called *God*, not by catachresis, but in the strict and rigorous meaning of the term; that the most ancient Fathers of the Church always taught the divinity of the Word, and that they derived the idea from the Holy Scriptures alone, and not from the Platonic philosophy as many have asserted. On the contrary, it is held that the Hebrew conception of the *logos* is of independent origin, though it was natural that in the New Testament the Greek word should be adopted to express it. Some of the opinions of modern theologians on the meaning of the *logos* are as follows: It is necessary, some say, in order to understand the true meaning of *logos*, to begin with the examination of Wisdom (*sophia*), which was previously used to express the same notion (See the Book of Proverbs, viii. 1, seqq., and the book of Wisdom, vii. 22, seqq.). The poetical author of the Proverbs does not imagine a person separate from God, but only an interior power of God, because, in his time there could be no idea of being proceeding from God, the Jews having borrowed this notion at a later period from the oriental doctrine of emanations. The author of the book of Sirach (xxiv. 3) first uses "The Word" (*logos*) of God as equivalent to "Wisdom" (*sophia*), to signify the almighty power of God. The Word being an act of wisdom gave rise to the symbol John speaks of the *logos* in the beginning of his Gospel only, and afterward uses the expression *pneuma tou theou*. From his representation, the following positions have been deduced: the *logos* was (a) from the beginning of all things (comp. Proverbs viii. 22; Sirach xxiv. 9); (b) from the beginning with God (comp. Sir. i. 1; Wisd. Sol. x. 16; ii. 14; Sir xxiv. 12). St. John, therefore, says those who thus interpret him, had the same idea of the *logos* as the apocryphal writers; for the circumstance that the latter ascribe to the *logos* the creation of all things, while St. John leaves this point undecided in his *en archē ēn* (in the beginning was) does not amount to a contradiction. Others, particularly the earlier commentators, understand by *logos* the Deity himself, that is, the second person of the Deity (according to St. John viii. 58). But those who adhere to the former opinion maintain that this is in contradiction to John xiv. 28; xii. 49, 50; v. 19, 20; and that he understood by *logos* only a power of God, which was communicated to Jesus, on account of which he could claim divine attributes and yet call the Father, as the source of this power, greater than himself. Others, as Herder,

LOGWOOD—LOKI

Paulus, Eckermann, understand by *logos* the Word of God, which, in the Old Testament, as the expression of the will of God, is the symbol of his creative power (Gen. i., et seq.). The later Jews represented the divine omnipotence by the Word of God. But it is maintained, on the other hand, from the manner in which John speaks of the *logos*, that he understood by it not merely omnipotence, but the Omnipotent. Others following the Fathers of the Church, particularly Eusebius, understand by *logos* an independent substance, external from God, like the *nous* (intellect) of Plato. But this again, it is said, involves an error, because Plato means by *nous* only a power of God. Still others, as Mosheim, Schlegel, Jerusalem, declare with Irenaeus the *logos* of St. John to be identical with the *logos* of the Gnostics; but it is objected that John did not conceive of a plurality like that in the doctrine of aeons. Lange considered *logos* equivalent to the *sophia* of the Old Testament, and that to the *logos* of Philo, and as a distinct person from God; but, say the others, *sophia* is not something distinct from God. Paulus, in his Commentary, also identifies the *logos* of Philo with that of St. John. But it is said, on the other hand, that John cannot be supposed to have been acquainted with Philo's notion, as it was not an opinion current at the time, and that the view of the apocryphal writers is more in harmony with his; moreover, that if St. John means anything more than an original, external power in God, his "was God" (St. John i. 1) would imply dualism. Doderlein and Storr translated the word *logos* by *doctrina*, the abstract being put for the concrete, *doctrine* for *teacher*, as in Gen. xlii. 38; 2 Sam. xxii. 23; Luke iv. 36. According to others, *ho logos* means *ho legomenos* (the promised). The ancient philosophers often distinguish two *logoi*, an interior in God or man which merely thinks (*logos endiathetos*), and an exterior or uttered (*logos prophorikos*).

Log'wood, the heart-wood of the *Hæmatoxylon Campechianum*, a leguminous tree which grows wild, in moist places, along the eastern shores of Mexico and Central America. From its abundance in some parts near the Bay of Campeachy it is sometimes called *Campeachy-wood*. The leaves are pinnate; the flowers small, yellowish, and disposed in axillary racemes at the extremity of the usually spinous branches. The wood is red, tinged with orange and black, so heavy as to sink in water, and susceptible of receiving a good polish; and it yields an extract much used in dyeing. (See DYES.) Though cultivated to some extent in Jamaica, the logwood of commerce is chiefly obtained from Honduras, where the cutting of it forms an extensive but unhealthy branch of business. Haiti and San Domingo also produce much. The finest kind comes from Campeachy, the inferior qualities from Honduras and Jamaica, to which island it is not indigenous, but where it grows abundantly since its introduction. In the preparation of this wood for use, the trees, which are from 20 to 50 feet high, are cut down, the bark and alburnum removed, and the hard centre parts cut up into 3-foot-long logs. It is afterward hewn into much smaller pieces, and ground or rasped to small chips. The aqueous extract is muddy and of a reddish-brown color. By acids the red

color is made paler; by alkalies it is converted to purple. Salts of iron, aluminum, and lead give precipitates of a blue, violet, or purple color. Logwood is chiefly consumed in dyeing cotton cloth, silk, wool, and leather; by mordanting the fabric with iron, black is produced; with alumina, violet and lilac; with copper, blue; and with chromium, a black or green—the exact tint depending on the composition of the mordants and logwood liquors, and the mode of application. The coloring power of logwood depends chiefly on a crystalline ingredient called *hæmatoxylin* (q.v.). In medicine both the extract and the decoction of logwood are used to some extent. The former is prepared by exhausting the wood with boiling water, filtering, and evaporating to a thickish syrup; the latter is the watery extract of the wood along with some cinnamon. Both are used as astringents in diarrhoea and dysentery.

Lohengrin, lō'ēn-grēn, the hero of an old German poem, written in the end of the 13th century. Ruckert's edition (1857) of the poem is the best. The poem is a continuation of Wolfram von Eschenbach's 'Parzival.' Wagner made it the subject of his great opera, 'Lohengrin' (1848).

Loir, lwar, France, a northwestern river which rises in the lagoon of Cernay in the Eure-et-Loir department, traverses the departments of Loir-et-Cher and Sarthe, and after a partly navigable course of 180 miles, flows into the Sarthe, five miles above Angers.

Loire, lwar (anc. *Liger*) France, the largest river of the country, dividing it into two nearly equal portions. It rises on the western slope of the Cévennes, in the department of Ardèche, and flows generally northwest and west to its outlet in the Bay of Biscay below Nantes. Its principal affluents on the right are the Arroux, Nièvre, Maine, etc.; on the left the Allier, Vienne, Cher, Indre, etc. Below Nantes, it is more a tidal estuary than a river, and is studded with islets. Above Nantes navigation is much impeded by shallows. Its whole course is about 645 miles, of which about 450 miles are navigable. The river is subject to disastrous inundations, and dikes (levées) have been constructed along its course. It is connected by canals with the Saône, Seine, and Vilaine.

Loja, lō'hä, Ecuador, city, capital of the province of Loja, in the southwestern part of the republic; about 50 miles from the Pacific. Its altitude is nearly 7,000 feet. It was founded in 1546. The beautiful scenery and mild climate make it a desirable residential city. It has some manufacturing. It is the seat of a college, and has a number of excellent secondary and elementary schools. Pop. 10,000.

Lokao, a dye, originally imported from China under the name of Chinese green, but now extracted from the berries of the common buckthorn. It contains 30 per cent of mineral matter. Pure lokao, obtained by treating the crude dye with solution of ammonia carbonate, filtering, and precipitating with alcohol, is a compound of ammonia with a pure blue coloring matter called lokain. An aqueous solution of crude lokao dyes cotton a pale green, but gives to wool and silk a pale bluish-gray.

Loki, lō'kē, in mythology, the god of strife and spirit of evil. He artfully contrived the

LOKMAN—LOMAX

death of Balder, when Odin had forbidden everything that springs "from fire, air, earth, and water" to injure him. The mistletoe not being included, was made into an arrow, given to the blind Höder, and shot at random; but it struck the beautiful Balder and killed him. This evil being was subsequently chained with 10 chains, and will so continue till the twilight of the gods appears, when he will break his bonds; then will the heavens disappear, the earth be swallowed up by the sea, fire shall consume the elements, and even Odin, with all his kindred deities, shall perish.

Lokman, lök-män', a name that figures in the proverbs and traditions of the Arabians. According to tradition Lokman was a scion from the stock of Ad, and was once sent with a caravan from Ethiopia to Mecca to pray for rain in a time of great drought. But God's anger destroyed the whole family of Ad except Lokman, the only righteous one, whereupon the Creator of the world gave him his choice to live as long as the dung of seven gazelles, which lay in an inaccessible hole in a mountain, should last, or for a period equal to the lives of seven successive vultures. Lokman chose the last, and lived for an almost incalculable length of time. The fables bearing the name of Lokman were for the first time made known to Europe through the press in 1615. They were first published in Arabic, with a Latin translation, were afterward appended to an Arabic grammar, published by Erpenius at Leyden, and have since gone through many editions. The most complete manuscript of the fables of Lokman is in the library of the Vatican, in Persian.

Lollardism, löl'är-dizm, in Great Britain, the tenets of the followers of John Wyclif. The views of Wyclif underwent a process of development as his researches and experience extended, and were by no means the same at all periods of his life. In so far as they departed from Roman Catholicism, they approached and, in some cases, went beyond what subsequently became the doctrine and discipline of Calvinism or Puritanism, commingled with an antagonistic element, Erastianism. Among the articles pronounced "heretical" by an assembly of ecclesiastical notables, convened in London in 1382 by Wm. Courtnay, archbishop of Canterbury, were these:

" 1. That the substance of material bread and wine doth remain in the Sacrament of the Altar after consecration.

" 3. That Christ is not in the Sacrament of the Altar truly and really in His proper corporeal person.

" 5. That if a man be only contrite, all exterior confession is to him superfluous and invalid.

" 7. That it hath no foundation in the Gospel that Christ did ordain the mass.

" 8. That if the Pope be a reprobate and an evil man, and consequently a member of the devil, he hath no power over the faithful of Christ given to him by any, unless, peradventure, it be given him by the emperor.

" 9. That after Urban VI. none other is to be received as Pope, but that Christendom ought to live after the manner of the Greeks under its own laws.

" 10. That it is against the sacred Scriptures that ecclesiastical persons should have any temporal position."

Among 14 articles adjudged to be "erroneous" were the following:

" 13. That a prelate or bishop excommunicating a cleric who hath appealed to the king or the council of

the realm, in doing so is a traitor to the king and the realm.

" 15. That it is lawful for any deacon or presbyter to preach the Word of God, without the authority or license of the Apostolic See, or of a Catholic bishop or of any other recognized authority.

" 17. Also that temporal lords may at will take away their temporal goods from churches habitually delinquent.

" 18. That tithes are pure alms, and that parishioners may for the offenses of their curates detain them, and bestow them on others at pleasure, and that tenants may correct delinquent landlords at will.

" 24. That friars are bound to get their living by the labor of their hands, and not by begging.

See also DOLLARDS.

Lollards, löl'ardz, a name which arose in the Netherlands in the 14th century, and which during that and the following century was applied somewhat indiscriminately as a term of contempt to various sects or fraternities deemed heretical by the Roman Catholic Church. Different accounts are given of the derivation of the name. According to one opinion the name was first applied to a fraternity formed about the year 1300 at Antwerp, the members of which devoted themselves to the care of the sick and the burial of the dead, and were called Lollards from the Low German *lollen* or *lullen*, meaning to sing in a low tone, from the subdued and plaintive dirges that they were in the practice of singing while accompanying dead bodies to the grave. According to another opinion the name was first bestowed upon the followers of one Walter Lollard, who preached peculiar doctrines both in England and on the Continent between 1315 and 1322, till in the latter year he was burned as a heretic. Whatever may have been the origin of the name, it became well known in England about the end of the 14th century, when it was applied to the followers of Wyclif. See LOLLARDISM.

Lolos, löl'öz, an aboriginal fair-complexioned people of China, inhabiting the Ta-liang-shan mountainous country, lying between the Yangtse River on the east and the Kien ch'ang valley on the southwest in Sze-chuen, and also found scattered on the Burmese and Tibetan frontiers. They are divided into tribes governed by hereditary chieftains, and maintain an independent position, frequently warring on their peaceful Chinese neighbors, and making slaves of them. They are descendants of aborigines who were driven southward by the immigration and increase of the Chinese.

Lormami, lō-mä'mē, Kongo Free State, a navigable river of Central Africa which rises near Kazaidi (Msoa), and after flowing almost parallel with the upper course of the Kongo River, enters the latter at Isangui several miles below Stanley Falls.

Lom'ax, Lindsay Lunsford, American soldier: b. Newport, R. I., 4 Nov. 1835. He was graduated from the United States Military Academy in 1856, entered the 2d cavalry, but later resigned from the United States army, became a captain in the Virginia State troops, and 29 April 1861 was made captain in the army of the Confederate States and assistant adjutant-general to General J. E. Johnston. In February 1863 he was appointed colonel of the 11th Virginia cavalry, in July 1863 brigadier-general, and in August 1864 major-general. He commanded a brigade under Fitzhugh Lee, a division under Early, and 1865 was made commander of the valley district. He took part in

LOMBARD—LOMOND

all the battles in which his portion of the Army of Northern Virginia fought, and surrendered with Johnston at Greensboro, N. C. After the War he was employed in the war records office at Washington, D. C.

Lombard, lōm'bārd, Peter, also known under his Latinized name, PETRUS LOMBARDUS, Italian theologian: b. Lugelugno, near Novara, Lombardy, about 1100; d. Paris 20 July 1164. He was a scholar of Abelard, and traditionally the first doctor of the University of Paris. He then became a teacher of theology, and in 1150, bishop of Paris. In his 'Sententiarum Libri Quatuor,' which became the subject of almost countless commentaries, and until the Reformation had almost classical authority among theologians, he placed the opinions of the Fathers, particularly Augustine, in regard to doctrines under certain titles, and then stated the objections made to them and the answers given by church authorities, but without offering any judgment of his own. The name of his work has given him the surname of Master of Sentences. Consult 'Life' by Protois (1881).

Lombard Architecture. See ARCHITECTURE.

Lombard College, a coeducational institution founded, in 1851, in Galesburg, Ill., under the auspices of the Universalists. In 1903 there were connected with the school 24 instructors and 204 students. The library contains about 8,000 volumes. It has a preparatory department and a classical department. The degree A. B. is conferred on those completing the classical course.

Lombard Street, a short street in London, which received its name from having been the residence of the Lombards, the money-lenders of former times, whose usurious transactions caused their expulsion from the kingdom in the reign of Elizabeth. It is now chiefly occupied by bankers, and is a place of much importance in the London commercial world. It is the English equivalent of Wall Street.

Lom'bards, Longobardi, or Langobardi, a Germanic or Teutonic people who at the beginning of the Christian era were dwelling on the lower Elbe. They make little appearance in history till the 6th century, when, under their king Alboin, they entered Italy in April 568, and, with the help of Saxons and others, conquered the northern portion, which hence received the name of Lombardy. From 713 to 744 the Lombards had a powerful king in the person of Liutprant, who extended his sway, at least temporarily, over the whole of Italy. From that time the power of the Lombards gradually declined, and finally Charlemagne captured Pavia after a six months' siege, and put an end to the Lombard kingdom (773 or 774), the last monarch being Desiderius.

Lombardy, lōm'bār-dī, Italy, an ancient kingdom, now a northern *compartimento* embracing the eight provinces of Bergamo, Brescia, Como, Cremona, Mantua, Milan, Pavia, and Sondrio, with an aggregate area of 9,297 square miles and a population in 1901 of 4,282,728, or 460.66 to the square mile. It comprises that portion of Upper Italy which took its name from the Longobardi or Lombards. (See LOMBARDS.) After the fall of the Lombard kingdom this territory remained attached to the empire of Charlemagne and his successors till

843, when an independent kingdom of Italy arose, out of which in process of time a number of independent duchies and marquises (Friuli, Mantua, Susa, etc.) or republics (Venice, Genoa, Milan, etc.) were formed. When Austria acquired the duchies of Mantua and Milan these provinces were called Austrian Lombardy, a name which they retained till Napoleon formed in 1797 out of them and other districts the Cisalpine, afterward the Italian Republic, and at last, in 1805, the kingdom of Italy. By the Peace of Paris, 1814, and the act of the Congress of Vienna, 1815, Austria received back its old Lombard possessions; but in consequence of the war of 1859 was compelled to cede them to Victor Emmanuel, king of Sardinia, by the Peace of Zürich, and in the following year they became part of the kingdom of Italy.

Lombok', East Indian Archipelago, one of the Lesser Sunda islands, east of Java, between Bali on the west and Sumbawa on the east. Area 3,136 square miles. The island is mountainous and of volcanic origin. Between the two ranges which traverse the island, one of them rising to the height of 11,800 feet, there is a plain fertile in rice, cotton, maize, coffee, and tobacco. The upper and former ruling class are Brahmins, and the mass of the people, Mohammedans. The capital, Mataram on the west coast, was bombarded in 1894 by a Dutch expedition, since when the island is administered by a Dutch resident. Pop. 370,000.

Lombroso, Cesare, chā'zā-rē lōm-brō'zō, Italian scientist: b. Verona 1836. In 1862 he became professor of psychiatry at Pavia, and later of medical jurisprudence and psychiatry at Turin. He became widely known through his investigations of the abnormal human being, and through his theories deduced therefrom; theories which encountered great opposition and are not yet entirely accepted, but which formed in part the basis for the present criminal anthropology. He published numerous works, such as: 'The Criminal' (1887-95); 'The Man of Genius' (1890; Eng. trans. 1891); 'The Anarchists' (1895); 'The Causes of, and Contest against, Crime' (1902). Consult the study by Kurella (1892).

Lomond, Loch, lōH lō-mónd, Scotland, a beautiful lake in the counties of Stirling and Dumbarton. Its length is about 24 miles; the breadth at the lower or southern end, 7 miles, at the upper end less than half a mile. For 14 miles from the head the breadth does not exceed 1½ miles. The lake is almost entirely surrounded with ranges of hills; and its surface is studded with numerous islands. The principal hills are on the eastern side, where a branch of the Grampians culminates in Ben Lomond, 3,192 feet high, on the very border of the lake. Through the glens intersecting the surrounding hills, the drainage of the district flows into the lake by the Falloch, Endrick, Fruin, Luss, and other streams; and the river Leven at the southwestern extremity conveys the overflow to the Clyde. The greatest depth is in the narrower part of the lake, where in some parts it reaches 600 feet. Fish, including salmon, salmon-trout, pike, perch, eels, and powans, usually called fresh-water herrings, are abundant. Steamboats in connection with the North British and the Caledonian Railway ply on the loch.

LONDON

Lon'don, Jack, American author: b. San Francisco, Cal., 12 Jan. 1876. He was educated at the University of California which he left to go to the Klondike region, and in 1892 went to sea before the mast. He has tramped throughout Canada and the United States for sociological study, and spent some time in seal fishing in 1893. He won attention in 1900 by 'The Son of the Wolf; Tales of the Far North'; and his later works, 'The God of his Fathers' (1901); 'A Daughter of the Snows'; 'The Children of the Frost'; 'The Cruise of the Dazzler' (1902), have been popular.

London, England, the largest city in the world, the metropolis of the United Kingdom of Great Britain and Ireland, and of the British Empire, situated on both banks of the Thames River, about 40 miles from its mouth, the latitude and longitude of Saint Paul's Cathedral being respectively $51^{\circ} 30' 48''$ N. and $0^{\circ} 5' 48''$ W. Modern London consists of the conglomeration of former towns and villages in the counties of Middlesex, Surrey, and Kent, which, as encircling suburbs of the ancient cities and liberties of London and Westminster, in the course of time, chiefly during the 19th century, have become practically absorbed with them in a common urban aggregation, by the addition of miles of connecting streets of dwelling houses and other buildings. In 1855 a Metropolis Local Management Act was passed, defining for sanitary purposes, outside the nucleate city of London with 673 acres, 186 parishes covering an area of 74,839 acres, 31,562 acres being in the county of Middlesex, 23,123 acres in Surrey, and 20,064 acres in Kent. By the Local Government Act of 1888, this area was constituted the metropolitan county of London, and for administrative purposes was divided into 28 boroughs, including the city of Westminster, but excluding the city of London. Several of these boroughs are described under their respective headings.

Table of the metropolitan boroughs, with their size in acres and population in 1891 and 1901:

BOROUGHS.	Area acres	Pop. 1891	Pop. 1901
<i>North of the Thames.</i>

Woolwich.....	8,277	98,094	117,198
Total.....	75,512	4,228,317	4,536,063

The term London is therefore legally and properly applicable to the entire area within the county boundaries. But outside the county limits, the urban aggregation extends with numerous large and connected towns, to 15 miles around Charing Cross. These are embraced in the boundaries of the metropolitan and city police districts and constitute Greater London, bringing the total area to 443,421 acres with a population (1891) 5,633,806, (1901) 6,580,615.

Climate.—London is one of the healthiest of the large cities of Europe. The average annual rate of mortality per 1,000 in 1840-50 was 26.6; 1850-60, 24.4; 1860-80, 23.2. The death rate for the year 1901-2 was 17.6, little above that of all England. The mean annual temperature is about 50° , and the general range of the thermometer is from 20° to 81° ; the highest and lowest markings being, for the most part, in August and January respectively. The prevailing wind is the southwest, and there are few places in the kingdom where less rain falls. In the beginning of winter London is occasionally enveloped in fogs, which are especially dense in the lower parts, and greatly aggravated by the perpetual pall of smoke-laden air, overhanging the metropolis. This pall, estimated to weigh 7,000,000 tons, is occasioned by the general domestic and industrial use of bituminous coal. Even when this smoke-cloud does not take the unpleasant form of fogs it keeps the sunshine away to quite a considerable extent, in winter robbing London of fully half the sunshine it ought to enjoy, and giving to the metropolis that general gloom and begrimed aspect of buildings which is so depressing to visitors.

General Aspect, River, Bridges, Main Thoroughfares, etc.—London stands on alluvial deposits consisting of beds of clay and gravel, below which is the hard clay stratum known to geologists by the name of the "London clay," in the middle of the great chalk basin extending from Berkshire to the east coast. On the north bank of the Thames where the principal part of London stands, the site rises gradually at the rate of 36 feet per mile, while on the opposite bank the houses cover a nearly uniform and extensive flat, lying in some places several feet below the highest tides. Within the limits of London the Thames varies considerably in width. At Putney it is 550 feet, at Battersea 960, at Vauxhall 630, at Westminster 275 feet, at Waterloo 1,140 feet, while at Blackfriars it narrows down to 830 feet. At London Bridge it is 800 feet wide, and at Woolwich 1,470 feet wide. The bridge farthest down the river is Tower Bridge, just below the Tower of London—a bascule bridge which allows the passage of large vessels. London Bridge connects the city at King William Street with Southwark at the junction of Wellington Street and Tooley Street. About 500 yards further up the river stands Southwark Bridge, connecting the city and Southwark. About half a mile further west Blackfriars Bridge connects the city at Bridge Street with Southwark at Great Surrey Street. Waterloo Bridge, nearly half a mile above the former, including its approaches, supported on semicircular arches, is 2,456 feet long; it is perfectly level, and connects the Strand with the

LONDON

Waterloo road. Westminster Bridge crosses the river at the north end of the Houses of Parliament from Westminster to Lambeth. Further up the river Westminster and Lambeth are again connected by Lambeth and Vauxhall Bridges. The Chelsea Suspension Bridge connects Chelsea and Pimlico on the north side with the Battersea Park on the south. The Albert Bridge connects the Chelsea Embankment with Battersea to the west of Battersea Park; and the Battersea Bridge unites Chelsea and Battersea a little further west. Putney Bridge, a magnificent structure of granite, connects Fulham and Putney; and Hammersmith Bridge, the last in London, connects Hammersmith with Barnes. There are also six railway bridges across the Thames. One of them, at Charing Cross, displaced the old Hungerford Suspension Bridge, but is provided with a footway on one side, so that the original communication is preserved. Another bridge, belonging to the same line of railway, crossing the river from Cannon Street, City, is similarly provided. The two railway bridges at Pimlico, which look like one, belong to the London, Brighton, and South Coast Railway Company, and the London, Chatham, and Dover. The latter company owns a bridge close to Blackfriars Bridge. New bridges are building at Vauxhall and Kew, while that designed to be built at Lambeth is said to be as notable a combination of art and utility as the famous Alexander III. bridge in Paris. The once famous Thames tunnel, 2 miles below London Bridge, opened in 1843 as a roadway under the river, now serves as a railway tunnel. A subway under the river, lined with iron hoops, connects Tower Hill and Tooley Street, Southwark; and there is a great tunnel for foot-passengers and vehicles between Blackwall and East Greenwich. An underground electric railway to South London passes under the river at London Bridge. Besides these there are steam-boat ferries between Greenwich and the Isle of Dogs, and between North and South Woolwich.

Since the passing of the Metropolis Management Act of 1855 great changes have been made in the condition of London. The gigantic operations connected with the sewerage of London and the embankment of the Thames, from Blackfriars to Chelsea on the north side, and from Westminster Bridge to Lambeth on the south, have produced great changes, while important lines of streets have opened up districts formerly almost inaccessible. These operations have also absorbed the former little rivers and rills, leaving only a corner, an alley, or a street, for example, Fleet Street, with their name for a monument. Further extensive main drainage works are being carried on which are estimated to cost \$15,000,000, and extensive street improvements sanctioned by Parliament, are in progress, among which the most important is the street from Holborn to the Strand through the Soho district and the widening of the Strand. In all the districts of London, and particularly in the City and West End, there has latterly been great improvement in the quality of architectural decoration and in public buildings, and stone has to a considerable extent replaced brick and plaster, though not so far as to change the aspect of some localities. Though some of the leading streets are wide, others are narrow and irreg-

ular. The decorative character of the streets about Lombard Street and the Mansion House in the City has been fostered by the growth of numerous banking and insurance companies, while the new office and store buildings in various quarters, especially the one opposite St. Mary le Strand, the hotels and apartment houses on the American steel structure plan, added an entirely new style of brick architecture.

"The City"—the historic centre of London—is bounded south by the Thames; it extends north to Charterhouse Square, east to Middlesex Street, and west to the New Law Courts. Till 1878 this last boundary was marked by Temple Bar, an old gateway crossing Fleet Street near the Temple; but in that year this structure was removed, and a memorial was erected on the site. The portion of the City inside the area of the former mediæval walls is known as "London within the walls"; and all the wards are bounded by the site of the old walls; the portion outside extends irregularly all around, and is known as "London without the walls."

Of the streets that run through Modern London the most important from west to east is that which enters from Kew into Hammersmith, and passing through Kensington, forms the finest of all the approaches to London. It stretches on through Brompton, Knightsbridge and Piccadilly, past fashionable Belgravia, with Kensington Gardens, Hyde Park and Paddington on the north, and with Apsley House and numerous other palatial edifices facing the Green Park, which constitutes its south boundary for about half the length of Piccadilly. This line is broken at the east end of Piccadilly, but passes by Regent Street (or by the Haymarket) and Trafalgar Square into the Strand, which continues it farther east and much nearer the river, and it stretches on past the Temple, along Fleet Street, Ludgate Hill, St. Paul's Churchyard, where it runs into Cannon Street, leading to the Tower on one side, and on the other into Cheapside, Poultry, Lombard Street, Fenchurch Street, Aldgate, and by Whitechapel road, and Mile-end road through the congested poorer districts to the county boundary at Bow. The next great artery between the west and east extends along the Uxbridge road from Acton, entering the county boundary at Shepherd's Bush and passing through Notting Hill, along Oxford Street, through Holborn and Newgate Street, where it joins the more south line above described, at the west end of Cheapside. Farther north is a third line, extending from near Kensington Gardens, through Oxford and Cambridge Terrace along the Marylebone and Euston road to Islington, and thence by the Pentonville and City road to Finsbury Square. Among the leading thoroughfares running north and south the extreme west is Edgware road, which enters the county at Kilburn, terminating at its south extremity in Oxford Street, from which it runs northwest, but communicating through Park lane with Piccadilly, a little to the west of which, from Hyde Park Corner Place, Grosvenor Place leads down to Buckingham Palace road, from which Vauxhall road forms a connecting line with the river. Park lane and Grosvenor Place on this line contain many of the most select residences of the aristocracy. East of Edgware road Regent Street

LONDON

from the Conquest to the present time. In the southwest angle is the Victoria Tower, supported on four pointed arches 60 feet in height; it is 75 feet square and 340 feet in height. There is also a tower in the centre, 300 feet high by 60 feet, surmounted by a lantern; and the clock tower, at the north end of the edifice, with its richly decorated spire, rises 320 feet. The House of Peers is an apartment 97 feet long, 45 feet wide, and 45 feet high; magnificently decorated throughout with carved oak paneling, a profusion of gilding, paintings in fresco, and richly stained glass windows. The House of Commons is a somewhat smaller apartment, fitted up in a much plainer style. Paintings in fresco and the water-glass medium, and statues of great statesmen have been added to the internal decorations; and a statue of the architect has been placed on the staircase leading up to the committee rooms. Westminster Hall, the most magnificent hall in the kingdom, 290 feet long, was built by William Rufus and improved by Richard II. It has recently been exposed on the west side, the ground laid out as an ornamental garden, and a fine statue of Cromwell erected therein. The hall is now not used except as a member's entrance to the House of Commons. In Old Palace Yard is an equestrian statue of Richard Cœur de Lion by Baron Marochetti, and a statue of Canning.

Palaces.—St. James', erected by Henry VIII. from a design by Holbein, at the foot of St. James' street, is an irregular and picturesque brick building. It is well adapted internally for royal levees and drawing rooms, which are held here during the fashionable season. Buckingham Palace, facing the west end of St. James' Park, was built by George IV., and consists, since the erection of the east front, of a quadrangular range of buildings. In the gallery, which is 160 feet long, are some good pictures. The king resides here occasionally in the spring and summer. Whitehall—the Banqueting House—designed by Inigo Jones in the Palladian style, is the only remnant of the ancient palace of Whitehall; the ceiling, painted by Rubens, is the most extensive work of that artist existing in the country. Kensington Palace, situated in Kensington Gardens, is a brick building of the Jacobean period, and was thrown open to the public by Queen Victoria shortly before her death. It was the birthplace of Her Majesty. Lambeth Palace, on the Surrey side of the river, opposite the Houses of Parliament, has been for many centuries the residence of the archbishops of Canterbury. It is a brick edifice, and comprises a great variety of styles in architecture, from Early English downward, and contains a library of 30,000 volumes. Fulham Palace, the residence of the bishops of London, is a building of no architectural pretension. It is pleasantly situated on the Thames, and at one time had extensive and well-timbered grounds. Greenwich Palace, once the home of the Tudor and Stuart sovereigns, is a stone building of considerable beauty, now used as a training school for the navy.

Government Offices.—These are mostly situated in and near Whitehall. The Treasury, Home Office, and Education Department occupy one range of buildings, which have been improved by a uniform and handsome façade.

The India Office and the Local Government Board faces St. James' Park. The Horse Guards, which are somewhat nearer Charing Cross, have little to admire in their external appearance, but opposite, and next to the Banquet Hall of the old Whitehall Palace, from the window of which Charles I. stepped to his execution, rises the New War office, and farther on the New Admiralty office. An extensive pile of government offices, for the Foreign Office and the Colonial Offices, has been erected in Downing Street. The style is Italian and the building exhibits a large amount of decorative detail, part of it in red and other colored marbles and granites. Some of the public offices are in Somerset House, once a royal palace of Charles II. It has a spacious and handsome quadrangle, finished in 1782, from designs by Sir W. Chambers: its north façade, 200 feet in length, faces the Strand; and its south front, 800 feet long, overlooks the river. The Post-office, near St. Paul's, is a spacious and handsome building. It is 390 feet long, 130 feet wide, and 64 feet high. Its façade, which is toward St. Martin's-le-Grand, has three Ionic porticos. A supplemental building for telegraph and other business occupies the opposite side of St. Martin's-le-Grand. The Mint, a stone building of the ordinary Georgian architecture, finished in 1810, stands on Tower Hill, and occupies about 10,000 square yards. The royal arsenal and dockyard for military stores is at Woolwich.

Courts of Law.—London is the seat of the supreme courts of the kingdom. Several of these were long accommodated at Westminster Hall, but in 1883 were removed to the New Law Courts at the junction of the Strand and Fleet Street. This great building occupies an area of nearly four acres. It is of a somewhat heavy mediæval character, a large western tower being its chief feature. The Old Bailey, adjoining the famous Newgate Prison, has, with the latter, been demolished to make way for the palatial Sessions House of the City of London. It is the central criminal court for the trial of prisoners who have committed serious offenses in the metropolitan district. One or more of the judges of the law courts sit here also in the old court, while the new court is presided over by the recorder and common sergeant of the City of London. There are numerous county courts within London for the trial of small debt cases. Besides the above there are also the Clerkenwell Session house; the city police courts, which are held at the Mansion House and Guildhall, and are presided over by the lord-mayor and one of the aldermen; and numerous police courts, each of which is presided over by a barrister of at least seven years' standing. The Inns of Court as they are called are four, the Inner Temple, Middle Temple, Lincoln's Inn, and Gray's Inn. Every law student, before he can be called to the bar, has to be entered as a member of one of these inns, and to dine a certain number of times in the common hall. The Inner and Middle Temple are close to Temple Bar, between Fleet Street and the river. The roof of Middle Temple Hall, built in 1572, is considered the best specimen of Elizabethan architecture in London. Lincoln's Inn is situated between Chancery Lane and the extensive square called Lincoln's Inn Fields,

LONDON.

1

1. Trafalgar Square.

2. Houses of Parliament.

LONDON

now open as a public garden. A handsome hall and library in the Tudor style, from the designs of Hardwick, have been erected in the gardens. Gray's Inn stands on the north side of Holborn. The gardens, first planted about 1600, were a fashionable promenade in the time of Charles II., and for some time after. The other "inns," Staple Inn, Barnard's Inn, Furnival's Inn, Clifford's Inn, New Inn, Sergeant's Inn, are now all in private hands and not connected with the law.

Clubs.—Many of these establishments, having most elaborate and ornate buildings, are among the principal architectural features of West London. They are situated chiefly in and near Pall Mall and vie with each other in elegance and luxury. The principal are: the Atheneum, possessed of a fine library, and having a great many artists and men of science and letters among its members; the Army and Navy, the United Service, the Guards', and the Junior United Service; the Carlton, the great Tory club, standing side by side with the Reform club in Pall Mall, the former numbering 1,800 and the latter 1,400 members; the Junior Carlton; the Oriental; the Travelers'; Brooks', one of the oldest of the clubs; White's, a still older club, much frequented by the Conservative nobility; the Conservative; the Devonshire; the Oxford and Cambridge; the Garrick, frequented by lovers of the drama; and four political clubs, which have the largest numbers of members, the Constitutional having 6,500, the National Liberal 7,000, the Junior Conservative 5,500, and the Junior Constitutional 5,000. Clubs are rapidly extending in London, and many have been established of late years to meet special purposes.

Hotels.—The Grand Hotel, Trafalgar Square, occupying part of the site of old Northumberland House; the Victoria Hotel and Hotel Metropole in Northumberland Avenue; the Hotel Cecil in the Strand; the Savoy Hotel on the Embankment; the Carlton Hotel at the corner of the Haymarket; the Russell Hotel, occupying the greater part of the east side of Russell Square, recently built; and De Keyser's immense hotel at Blackfriars, are the most important and attractive. There are large hotels at Charing Cross and Cannon Street in connection with the South Eastern railway, at St. Pancras in connection with the Midland railway, and at Marylebone in connection with the Great Central railway, the last named being the largest and one of the handsomest in London. Also associated with railways are the Great Western hotel at Paddington; the Great Northern hotel at King's Cross; the Grosvenor hotel at Pimlico. Other large hotels are the Langham hotel, Portland Place; the Westminster Palace hotel in Victoria Street; the Salisbury hotel, in Salisbury Square, Fleet Street; the First Avenue near Gray's Inn; and the famous Ship hotel at Greenwich, where the ministerial whitebait dinner used to be held, while new hotels in London are being erected almost everywhere.

Theatres, Public Halls, etc.—The principal theatres are Covent Garden (the Royal Opera House), opened in 1858; Her Majesty's Theatre, Haymarket, the historic Drury Lane, the Haymarket, the Princess', the Lyceum (now being demolished), the Strand, the Adelphi, the Sur-

rey, the Gaiety (recently demolished), the Globe, the Opera Comique, the Pavilion, the Standard, the Vaudeville, St. James', the Savoy, the Avenue, the Comedy, Criterion, Terry's, the Lyric, the Garrick, the Shaftesbury, the Duke of York, the Prince of Wales', Wyndham's, and the Court. Local theatres have been built in many of the outlying parts of London. St. James' Hall, remarkable almost entirely for its interior, is chiefly devoted to musical entertainments of a high class. The Queen's Hall in Portland Place, and the Albert Hall at Kensington, are devoted to high-class music. Hanover Square Rooms were once famous as concert rooms. Exeter Hall, in the Strand, is occupied by the Young Men's Christian Association, and is used also for the annual May meetings of the different religious societies. The Freemasons' Hall in Great Queen Street, is well known, and Olympia, at West Kensington, is a large and imposing hall in an extensive area. The Congregational Memorial Hall, and the Agricultural Hall, Islington, the largest covered area in London, are also important buildings of this kind. The Empire and the Alhambra in Leicester Square are the chief of numerous music halls in London, where in general the entertainment is not of a very elevated description, though the improvement of late years is marked.

Markets.—These are numerous, but have generally little to attract either in external beauty or in internal arrangement. The principal ones are: Billingsgate for fish; the Borough Market, Southwark, and the famous Covent Garden for vegetables, fruit, flowers, and plants; Leadenhall for poultry, game, etc.; Deptford for foreign cattle; Smithfield for fresh meat, poultry, and fish; the Islington cattle market, in the Caledonian road. The Spitalfields market and the Woolwich market, for vegetable products, are included in the public markets. But London is inadequately provided. The city corporation own all the largest markets, and exercise charter rights to prevent others being erected. The result is that all retail markets are in the hands of costermongers, who line many of the most prominent of the public thoroughfares with their barrows and portable stalls, and who are under no public control as to the produce they sell.

Museums, Galleries, Libraries.—The British Museum (q.v.), founded in 1753, in Great Russell Street, is a spacious and imposing edifice, with a classical façade and sculpture in the pediment, built between 1823 and 1857. It contains an immense collection of books, manuscripts, engravings, drawings, sculptures, coins, minerals, stuffed animals, fossils, preserved plants, etc., and a magnificent collection of ethnographical objects, Egyptian, Assyrian, Etruscan, Greek, and other antiquities. An extensive building (about 650 feet long) has been erected in the South Kensington quarter for the accommodation of the natural history collections. The museum of the Royal College of Surgeons, on the south side of Lincoln's Inn Fields, a rather handsome building, contains a magnificent collection of human skulls from all parts of the world, and many curious surgical preparations. The Soane Museum, on the north side of Lincoln's Inn Fields, possesses many valuable objects, consist-

LONDON

ing of books, paintings, prints, MSS., drawings, maps, models, plans, etc. The Dulwich College gallery contains many interesting pictures left by Alleyne, the contemporary actor of Shakespeare's age. The great South Kensington or Victoria and Albert Museum contains most valuable collections, carefully arranged for purposes of instruction, in connection with which are the schools and headquarters of the Department of Science and Art. Museums have also been established at Bethnal Green and in South and North London, and quite recently Hertford House, with its priceless art treasures, the gift of Sir Richard Wallace, and the Horniman Museum at Forest Hill, the gift of P. J. Horniman, have been added to the London museums. The chief picture gallery in London is the National Gallery, on the north side of Trafalgar Square. It contains about 1,200 paintings, acquired partly from donations, partly by purchase. The National Portrait Gallery is a collection of over 1,100 portraits, busts, and medallions brought together since 1858. For this collection a new building besides the National Gallery has been provided by private munificence; and the Tate Gallery of British Art, on the Thames Embankment has been similarly acquired. The Royal Albert Hall of Arts and Sciences, a memorial to the late prince consort, is a huge building between the Horticultural Gardens and Kensington road. It was erected for the purposes of science and art, musical performances, exhibitions, etc. It is chiefly used for concerts and is capable of accommodating an audience of 8,000, while the orchestra itself accommodates 1,000 performers. The building also contains a picture gallery. In Hyde Park, immediately opposite this building, is the Albert Memorial. The north wing of Burlington House, Piccadilly, has been granted to the Royal Academy and a suite of rooms built in the rear of it for exhibitions. The east and west wings of Burlington House are occupied by various learned societies, the Royal Society, the Society of Antiquaries, and others. Near the South Kensington Museum and the Albert Hall is the splendid block of buildings of the Imperial Institute, with its various permanent collections and exhibitions, and institutions. Besides the British Museum library, the chief libraries are: Lambeth Palace library, the Guildhall library, Sion College library, the London library (subscription), London Institution library, and in addition large circulating libraries and many free public libraries supported by taxes.

Educational Institutions.—At the head of these stands the London University (q.v.) which promises to become the foremost scientific university in the kingdom. Other institutions are denominational colleges for theology (in some combined with general education); the Royal Naval College, Greenwich; the Royal Military Academy, Woolwich; the Royal College of Science; the medical schools attached to the hospitals; Royal Academy of Music; Royal College of Music; Trinity College, chiefly for music; several colleges for ladies, etc. Among the grammar and secondary schools are: St. Paul's School, founded in 1509, which provides a free education for 153 boys, with scholarships to Oxford and Cambridge; the Merchant Tailors' or Charterhouse School (q.v.); Christ's Hospital

(q.v.); Westminster School, founded by Queen Elizabeth in 1560; University College School, King's College School, City of London School, Mercers' School, and schools of the several city companies. Besides the above and numberless private schools, there are the City and guilds institutions for technical education, many high schools for girls, many free schools, numerous schools of the National Society, and more than 400 schools of the London School Board. Several polytechnics and centres of technical education have been equipped and supported by the London county council, who have also established a system of county scholarships for students, which promises to be of great value.

Scientific Associations, etc.—Associations for promoting science, art, learning, etc., are exceedingly numerous. The chief are the Royal Society, Burlington House, founded in 1660; the Society of Antiquaries, in the same building, originally founded in 1572; the Royal Academy (of painting, etc.), in Trafalgar Square, founded in 1768; the Royal College of Physicians, founded by Linacre, physician to Henry VIII., in 1518; the Royal College of Surgeons; the Royal Geographical Society, with a choice geographical library and large collection of maps; the Institution of Civil Engineers; the Royal Institute of British Architects, possessing a good library of architectural works; the Royal Institution of Great Britain, established in 1799; the Royal Horticultural Society, which possesses the botanic gardens in Regent's Park, as also at South Kensington and at Chiswick; the Royal Astronomical Society; the Royal Asiatic Society; the British Association; the Zoological Society, with its collection of animals in Regent's Park; the Geological Society, and the Anthropological Institute.

Hospitals and Charitable Institutions.—Besides the three great endowed hospitals: St. Bartholomew's, in West Smithfield; Guy's, Southwark; and St. Thomas', Lambeth, occupying a large and splendid range of buildings on the Thames Embankment opposite the Houses of Parliament; there are the London Hospital, St. George's Hospital, the Middlesex Hospital, Westminster Hospital, Charing Cross Hospital, King's College Hospital, University College Hospital, St. Mary's Hospital, and Royal Free Hospital, all with medical schools attached. Other general hospitals are: The Great Northern Hospital, the West London Hospital, and the Metropolitan Hospital; besides the German Hospital, Dalston; hospitals for special diseases, as consumption, fever, cancer; hospitals for women, for children, etc. Bethlehem Hospital (Bedlam), in St. George's Fields, south of the river, is the chief hospital for lunatics; St. Luke's Hospital is also for insane patients. The Foundling Hospital (see FOUNDLING) is rather an asylum for illegitimate children generally than a hospital for foundlings. Chelsea Hospital and Greenwich Hospital are institutions by themselves.

Prisons.—There are altogether about a dozen criminal prisons. The most celebrated of these, Newgate, near St. Sepulchre's Church, a gloomy and massive structure, the scene of a great many executions, was pulled down in 1903. Millbank penitentiary, or prison, an immense brick edifice with external walls enclosing upward of 16

LONDON

acres, has also been demolished, and the site utilized partly for workmen's dwellings and partly for the Tate picture gallery. The chief existing prisons are Clerkenwell prison, the Wandsworth prison, Holloway prison, for females, debtors, etc.; the Westminster House of Correction, for female prisoners, in Tothill Fields, built on the Panopticon principle, with a courtyard in the centre 250 feet in diameter, and conducted on the silent system; the model prison, Pentonville, containing 1,000 cells, in which the inmates are taught useful trades; Wormwood Scrubs prison, a large building standing, almost isolated on the borders of London.

Squares and Public Monuments.—The squares of London are characteristic; many of them are of great beauty and extent, and planted with shrubbery. Among them are: St. James' Square, north of Pall Mall; Eaton, Belgrave (10 acres), Grosvenor, Portman, Cavendish Squares, all in the west end; Russell Square (10 acres), Bedford, Bloomsbury, Tavistock, and Euston Squares, in the west central part of the town; Trafalgar Square, at Charing Cross, fronting one of the principal thoroughfares and adorned with public buildings, fountains, the Nelson Column, and statues of Charles I., George IV., and others. The most conspicuous public monuments are: "The Monument," on Fish Street Hill, London Bridge, a fluted Doric column 202 feet high, erected in 1677 in commemoration of the great fire of London; the York Column, at the south end of Waterloo Place, a plain Doric pillar of granite 124 feet high, surmounted by a bronze statue of the Duke of York; a fluted Corinthian column in Trafalgar Square, 176½ feet high, raised in honor of Nelson, and surmounted with a colossal bronze statue of the hero, having the pedestal decorated with bronze sculptures in high relief, and four magnificent lions, by Sir E. Landseer, at the angles; the Albert Memorial, Hyde Park, the most splendid and costly monument of recent times, being a Gothic structure 176 feet high, with a colossal seated statue of the prince under a magnificent canopy elaborately sculptured and adorned; and the projected magnificent memorial to Queen Victoria with its beautiful surroundings in front of Buckingham palace. There is a statue of the Duke of Wellington in front of the Exchange, and a statue of Sir Robert Peel at the top of Cheapside. Statues of Sir Charles J. Napier, Sir Henry Havelock, and General Gordon stand in Trafalgar Square. On the Thames Embankment, not far from the Temple, now stands the Egyptian obelisk known as Cleopatra's Needle; and west of it are statues of Robert Raikes, the founder of Sunday schools, General Outram, John Stuart Mill, and others. In Waterloo Place is a memorial to the Guards who fell in the Crimea, and here is also a statue of Sir John Franklin. An equestrian statue of the Duke of Wellington at Hyde Park corner was erected in 1888. A monument to Sir Hugh Middleton, who brought the New River water to London, has been erected on Islington Green. Among other memorials are: The Westminster Crimean Memorial, in the open space at the west of the Abbey; the Peabody statue behind the Royal Exchange; an equestrian statue of Prince Albert in Holborn Circus, a statue of

Carlyle on Chelsea Embankment, and of Lord Beaconsfield in Westminster Palace Yard.

The Parks.—Of these the finest and most fashionable is Hyde Park (q.v.), which lies between the Uxbridge and Kensington Roads, and contains about 400 acres. Kensington Gardens, with which Hyde Park communicates at several points, are beautifully wooded and finely laid out. Here carriages are not admitted. St. James' Park (83 acres) extends from Buckingham Palace to the Horse Guards, and in its centre is an ornamental sheet of water, studded with islets covered with trees and shrubs, and around which swim a great variety of aquatic fowls. The Green Park, 71 acres in extent, lies between St. James' Park on the south and Piccadilly on the north. Regent's Park, on the north side of London, covers an area of over 400 acres. Round the park is a drive nearly three miles long, and an inner circular drive encloses the Botanic Gardens. At the north end are the Zoological Gardens, to which a fine broad avenue leads along the centre of the park. Battersea Park is on the south bank of the Thames, opposite to Chelsea Hospital. Victoria Park is on the northeast of London, laid out and planted as a place of recreation for the poorer inhabitants of this part of London. Southwark Park is another artificially formed recreation ground. Greenwich Park is one of the most delightful features of South London, and has great natural beauties; the famous Greenwich Observatory is situated here. There are many other parks acquired for use of the public during late years. Brockwell Park in Camberwell, Ravenscourt Park in Hammersmith; Finsbury Park and Clissold Park on the north borders of London, are the most extensive. But even more typically a part of modern London are the numerous and beautiful heaths and commons preserved for the public. Hampstead Heath on the north, Blackheath and Plumstead Common on the southeast, and Totting and Streatham commons on the south are the most extensive.

Places of Popular Resort.—There are various places of popular resort in London. The Exhibition at Earl's Court, a vast open-air entertainment accompanied by exhibits of special descriptions arranged in courts and buildings within the grounds, is the largest. Olympia at Kensington is of less magnitude. The Zoological Gardens and the Botanical Gardens, both in Regent's Park, are very largely frequented. The People's Palace, established by contributions of the benevolent, in the East End of London (Mile-end road), and opened in 1887, provides a hall for concerts and other entertainments, a library and reading rooms, swimming baths, gymnasiums, social meeting rooms, winter garden, technical schools, etc., its object being the moral and intellectual improvement of the working classes of East London. Outside London there are other places of this description. The most important is the Crystal Palace (q.v.), at Sydenham, formed to a considerable extent of the materials of the exhibition building of 1851, removed from Hyde Park. It was originally designed as a great educational museum of art, natural history, and ethnology; and its gardens and fountains were to rival or surpass those of Versailles. For years music has taken an important place in the

LONDON

arrangements of the palace. Entertainments of merely amusing character have also been largely introduced. A somewhat similar building is the Alexandra Palace, occupying a conspicuous site on Muswell Hill on the north. Kew Gardens (q.v.) on the west and Hampton Court Palace (q.v.) and grounds, built by Cardinal Wolsey and enlarged by William III., further out toward the southwest.

Lighting, Sewerage, and Water.—London is supplied with gas by eight separate companies. These companies include in their area of supply a considerable district outside London. Since 1886 a large number of electric lighting companies have come into existence, in 1901, 16 companies and 15 local administrations possessing statutory powers to supply electricity. The sewerage works with which the Metropolitan Board was charged, were formally opened in 1865. The system consists of lines of intercepting sewers on both sides of the Thames intersecting the old outlets which are retained for service during heavy rainfalls. It consists of three main lines on the north of the river, at different levels, called respectively the High Level, Low Level, and Middle Level Sewers; and of two on the south side, called High and Low Level Sewers. The lines on the north side converge at the Lea river, whence, after the Low Level sewage has been pumped to the higher level, the whole flows in three parallel brick culverts, built in an embankment upward of 5 miles in length, on to the Northern Outfall and reservoir, about 14 miles below London Bridge. On the south side the Low Level sewage is pumped to the higher level at Deptford, whence the whole is conveyed to a point near the mouth of the river. The total length of the sewers is 82 miles, and the area drained is 120 square miles, together with sundry small districts, accommodated by the London system. Considerable extensions are in progress. Works have been established for precipitating the sewage; the deposit after precipitation, amounting to 5,000 tons daily, is carried out to sea and deposited several miles from land. The metropolitan water supply has been considerably amended of late years. There are eight companies supplying London and an extensive area around extending into Middlesex, Essex, Kent and Surrey. The total quantity of water supplied by these companies amounts to over 200,000,000 gallons daily. The largest quantity is supplied by the East London Company. Rather more than 113,500,000 gallons of this total is supplied from the Thames river, 55,250,000 from the Lea river, 33,500,000 from springs and wells. By an act passed in 1852 all the companies making use of the Thames are obliged to draw from above the limit of the tidal flow. Even above this point the water is not free from pollution by the sewage of numerous populous towns, and by the drainage of richly-manured land. Means are adopted for storing the water, and it is all filtered through layers of gravel and sand before entering the mains; but the system of supply is liable to various objections, and the total quantity is inadequate to meet the entire wants of the population. Commission after commission, and committee after committee, have examined and reported on this important subject, but in 1896, 1897, and 1898, the whole east end of London

and much of the south suffered from want of proper water supply.

Cemeteries.—Extramural interment is of comparatively recent date. Kensal Green Cemetery, in which several royal personages have been buried, was opened in 1832; it occupies about 70 acres of ground, and is tastefully planted and laid out. Kensal Green Roman Catholic Cemetery occupies 30 acres. The cemeteries at Brompton, the Tower Hamlets, Bethnal Green, Nunhead, and Norwood are the only intra-mural places in which interments are permitted, excepting in the case of interments in St. Paul's and Westminster Abbey; and some of the cemeteries named would now be closed were they not provided with their special acts. At the Woking Cemetery, which occupies about 2,000 acres, the poor of several of the London parishes are buried, special railway accommodation being provided for cemetery traffic. Some of the parishes, as Marylebone and St. Pancras, and Paddington, have their own cemeteries. The City of London Cemetery is at Ilford, in Essex, and other cemeteries are also situated outside.

Communications.—The London population commands two systems of locomotion, namely, internal and external. The former has reference to the purely London requirements, and is by means of omnibuses, cabs, tramways, steam-boats, and railways; the latter has reference to the connection of London with the rest of the kingdom and the Continent, and is by canals, railways, and the Thames. The internal traffic of London has become almost overwhelming. There are 12,000 cabs, 3,000 omnibuses, 1,200 tramway cars, besides the Metropolitan, the Metropolitan District and the Electric Railway systems, and the local systems on other lines. These are extending in all directions. The great English railways long ago reached the limit of their ability to cope with suburban traffic in and out of London. The old underground railway was designed to be complete in an inner and outer circle, but the outer circle was found to be insufficient before it was built, while the inner circle does not even touch what might be called suburbs. Yet so long as it was without competition the two companies owning this system drew great dividends and ignored the demands of their dependent patrons for better service. Not until competition arose in the shape of the Central London electric tube railway did the directors of the District and Metropolitan lines bestir themselves. American enterprise in acquiring control of the District Underground brought a flood of underground railway schemes forward, and parliamentary committees have been kept busy deciding between rival schemes. They have been careful to reserve all manner of rights to the government, refusing, for instance, to grant any route unless the proposed company agreed to provide and maintain a subway for pipes and wires along its line. This is an effort to unravel the tangle of such things which the least upturning of the streets shows. These lines are also refused complete independence of each other, and are compelled to arrange transfers and joint time tables. There are now 52 miles of deep railways running and authorized, estimated to cost £500,000 per mile. The great objection in London to shallow tram-subways,

LONDON

such as are now used in Paris and in New York, is the necessity of torn-up streets for a long period, as well as the difficulty of disposing of the soil so near the surface. The tubes, after the fashion of burrowing animals, must necessarily dispose of their soil at the end of their tunnel only. It is safe to predict that in ten years it will actually be possible to traverse London by public conveyance more quickly than one could walk or go in a cab. Now, for lack of means, or of co-operation when there is means, the task is hopeless. The number of passengers in one year traveling by omnibus is nearly 200,000,000, and by trams nearly 300,000,000. Side by side with all this activity along the roadways, the Thames has almost been allowed to drop out of existence as a local travelers' route, for though small steamers ply from wharves and piers between Kew and Woolwich, the service is at present altogether inadequate. The principal railway stations are: The Great Eastern, Liverpool street, Bishopsgate; the London and North Western, Euston Square; North London, Broad street; Great Western, Paddington; the Great Northern, King's Cross; Midland, St. Pancras; Great Central, Marylebone; South Eastern, London Bridge, where there is a congeries of stations, Charing Cross and Cannon street; London, Chatham, and Dover, Ludgate Hill, and Victoria; the London, Brighton, and South Coast railway, Victoria and London Bridge; the South Western, Waterloo Bridge. Many of these stations communicate by the Metropolitan and District railways, distinct systems, but both popularly known as the "Underground," affording means of internal communication within the city. Many of the termini are elaborate piles of costly architecture, and have associated with them large and handsome hotels. The Thames affords communication by steam vessels with the most important points on the British and Continental coasts, as well as with all parts of the world.

Manufactures.—It is impossible within the limits of this article to specify the different kinds of articles manufactured in London. It contains the largest breweries, distilleries, and sugar refineries in the kingdom; was long the principal seat of silk weaving; has extensive manufactures in metal, including machinery of all kinds, plate, jewelry, watches, and brass work and an enormous production of books and prints. Millinery, the making of clothes and of boots and shoes are also extensive branches of industry. Besides these, there are cabinet making, coopering, coach building, leather working, hat making, ship-building, rope making, mast making, etc., all of which are departments of manufacture conducted on a large scale; and there are numerous extensive chemical works, soap manufactories, and dye works.

Commerce, Docks, etc.—The port of London extends from London Bridge to the Nore and is divided into the Pool, Limehouse Reach, Greenwich Reach, Blackwall Reach, etc. It is under the care of the corporation of the city for sanitary purposes, under the Thames Conservancy for navigation, and under all sorts of other authorities for various other purposes. It is probably the worst managed port in the world. The docks, some of which are of great

extent, are surrounded by wharves, sheds, storehouses, vaults, and warehouses of the most spacious kind. St. Katherine's docks, London docks, the West India docks, the East India docks, and the Millwall docks (in the Isle of Dogs) extend along the north side of the river at intervals from the Tower to Blackwall; and on the south side, between Rotherhithe and Deptford are the Surrey Commercial docks. The tide rises 18 feet at springs and 14 feet at neaps at the London docks; and the depth at low water, spring tides, on the outer sill of St. Katherine's docks is 10 feet. The largest of these older docks is the West India import dock, 2,600 feet long and 500 broad. The dock accommodation of the port was greatly increased by the construction of the Victoria and Albert docks, which follow next in order on the north side of the river (opposite Woolwich) and have a combined length of $2\frac{3}{4}$ miles, with a water area of 175 acres. The Victoria dock was opened in 1855, the Albert dock in 1880. The depth over the sill of the east entrance of the latter at high water is 30 feet. Besides these, there are now the splendid docks at Tilbury, on the Essex shore opposite Gravesend, constructed for the purpose of admitting the largest vessels at any state of the tide. Here there are a tidal harbor, graving dock, 3 miles of quays, sheds covering 20 acres, etc. The vessels belonging to the port in December 1900, numbered 1,252 sailing and 1,653 steam; aggregate tonnage, 1,716,616. Its exports of British and foreign produce in 1900 amounted to £91,502,552; the imports to £175,901,307. Out of 11,118 vessels that entered in the foreign and colonial trade in 1900, 5,999 were British, 1,343 Dutch, 1,133 Norwegian, 1,003 German, 444 Swedish, 369 Danish, 353 Belgian, 156 French, 124 Russian, 83 Spanish, 27 Italian, 22 Austro-Hungarian; 62 United States, the total of all foreign vessels being 5,119. For East and West India produce London is the great port; tea, sugar, tobacco, wine, corn, timber, tallow, hides, wool, and drugs form large items.

The amount of customs revenue received in 1900 was £11,388,560. The value of the imports is over one third, of the customs revenue about one half of the whole amount for the United Kingdom.

The following table gives particulars for 1900 of the shipping entering and clearing at the port of London from and to foreign countries and British colonies and coastwise:

1900	Sailing	Steam	Tonnage
ENTERED			
Foreign	1,443	7,965	7,153,431
Colonial	523	1,187	2,427,323
Coasting	4,094	10,602	5,972,147
Total.....	6,060	19,754	15,553,001
CLEARED			
Foreign	1,113	6,219	5,636,433
Colonial	235	536	1,483,240
Coasting	5,609	12,686	7,827,763
Total.....	6,957	19,441	14,947,436

Administration.—The most ancient civic officer of London is the lord-mayor of the city of London. He is annually elected from among the aldermen who have been sheriffs of the city, on 29 Sept. and installed in office on 9 Nov. when a procession takes place, called the lord-

LONDON

mayor's show. The court of aldermen consists of 26 members, including the lord-mayor. They are chosen for life by the taxpayers of the 26 wards into which the city is divided, each being the representative of a separate ward. They are properly the subordinate governors of their respective wards, under the jurisdiction of the lord-mayor, and preside over the business in the courts of Wardmote. The civic sheriffs, two in number, are annually chosen by the livery or general assembly of the freemen of London. The common council is a court consisting of 206 representatives returned by 25 of the wards in proportion to their relative extent; the 26th, or Bridge Ward Without, being represented by an alderman. The general business of this court is to legislate for the internal government of the city, its police, revenue, etc. The recorder is generally a barrister of eminence, appointed for life by the lord-mayor and aldermen as principal assistant and adviser to the civic magistracy and one of the justices of oyer and terminer. The "livery" of London is the aggregate of the members of the several city companies, of which there are 75. Of these, 12 are termed great companies and from one or other of them the lord-mayor was formerly chosen. In order of precedence they are: The Mercers, Grocers, Drapers, Fishmongers, Goldsmiths, Skinners, Merchant Tailors, Haberdashers, Salters, Ironmongers, Vintners, Clothworkers. Many of the companies are very rich and possess large halls. Besides the ancient city of London there are under the act of 1899, the 28 metropolitan boroughs, already enumerated, each of which for local purposes is governed by a mayor, aldermen, and council. The governing authority for the entire county of London is the county council, which consists of the chairman of the council, 19 aldermen, and 118 councillors, the latter being elected by the taxpayers of the several divisions, which are, however, not coincident with the boroughs. There are also two other governing bodies for the county, the School Board and the Metropolitan Asylums Board, the former elected by the taxpayers, the latter by the Boards of Guardians.

The Police.—The city police, confined to the city proper, is administered by the city corporation as a municipal force and numbers about 900 men. The metropolitan police is not municipal. It is administered by a commissioner appointed by the Home Office. It consists of over 15,000 men, whose central offices are New Scotland Yard, a massive building on the Embankment near Westminster bridge. Its area of jurisdiction extends for 15 miles from Charing Cross.

For postal purposes the authorities divide the major portion of Greater London into districts designated by their initial letters, E. C., W. C., W., S. W., S. E., E., N., N. W., signifying East Central, West Central, etc.

Sociology.—Statistics to March 1902 show that the population of Greater London at that date was 6,581,372. Of this number 1,202,072 were born in England (outside London), 56,605 in Scotland, 60,211 in Ireland and 38,899 in other parts of the British empire. The alien population numbers 79,804 males and 55,573 females. The average birthrate per 1,000 of population in

1901 was 29, as compared with 30.3 in 1891-1900, 32.3 in 1881-90, 35.5 in 1871-80, 35.4 in 1861-70 and 33.6 in 1851-60. There are in the city 1,033 females for every 1,000 males. Out of every 1,000 persons of marriageable age, 367 males and 372 females are unmarried. In 1900, 36,635 bachelors were married, 37,463 spinsters, 3,875 widowers and 3,047 widows. Of the total number of marriages 72 per cent took place in the Established Church, 16.8 per cent in the registry offices and 4.6 per cent in the Nonconformist churches. Of the 135,377 foreigners not naturalized British subjects, natives of Russia are the most numerous; Germany stands second, Russian Poland follows, France is fourth and Italy fifth. The Russians in London have increased since the last census from 12,034 to 38,117 —fully three-fold, that is—while Italy has doubled her contribution toward the population, now accounting for a round 10,000. The American invasion takes the form of 211 "actors."

History.—Though, by the evidence of its name and by archaeological remains, London was occupied by the Celtic Britons before the arrival of the Romans, it was not till the Roman era that it became a place of importance. There were probably two Roman Londons: the first destroyed by Boadicea and probably consisting of the area extending from near the Tower on the east by the course of the Langbourne (now preserved in Langbourne ward) on the north, by the course of the Walbrook on the west, and the Thames on the south; the second probably coincident with the mediæval walled city. The Roman walls were destroyed by the Danes and were restored by King Alfred. After the Romans left Britain, London assumed a certain amount of independence and throughout the Anglo-Saxon period it appears to have supported the monarch who was acceptable to the rest of the kingdom. Alfred was the first king of the Anglo-Saxons who thoroughly understood the importance of its military position. It suffered by fire in 764, 798, and 801. It was sacked by the Danes, who obtained a considerable settlement in Southwark and on the western boundary of the city beyond the Ludgate. At the Conquest London treated with and finally submitted to William. William's first act was to dominate the city by building his military stronghold, the beginnings of the Tower of London. He then granted the city its ancient rights by a charter, which is still preserved; on the accession of Henry I., a new charter was granted and the charter grants increased considerably under the Plantagenets, while its municipal privileges were made the standard for governing many of the municipal boroughs in the provinces. London sided with Stephen against Matilda, took part in the struggle against John for Magna Charta, was severely oppressed by Henry III., strongly supported Edward IV. and the Yorkish party in the wars of the Roses, and was faithful to Richard III.; it equipped and despatched ships to the navy collected to fight the Spanish Armada, and its citizens, officered by the aldermen of the city, fought for the Parliamentarian side against Charles I. Under the later Stuarts and the Georges it became more political than municipal and lost much of its "ancient

LONDON

power. In the reign of Henry II. the walls on both sides of the river are described in a contemporary account as supplied with numerous towers. London Bridge, erected instead of a wooden one, was begun in 1176 and finished in 1209. This was to a great extent the same that was taken down in 1832. In 1218 the forest of Middlesex was cleared, and that portion of London north of the city began to be built. In the year 1328 the village of Southwark was incorporated with the city, as it had previously served as a place of refuge for malefactors. In 1349 and 1361 London was visited by the plague. In 1381 broke out the rebellion of Wat Tyler, who fell by the hands of the lord-mayor, hence the dagger on the city arms. In 1416 street lamps were introduced; in the same century some of the principal streets were paved, and wooden houses began to be replaced by others of brick. In the next century improvements were continued, and Westminster was connected with the city by a row of noblemen's mansions along the river, the last of which, Northumberland House, has made way for the road leading from Trafalgar Square to the Embankment. In the 17th century, Spitalfields was covered with houses, and the space north of the Strand as far as Holborn, and from Temple Bar to St. Martin's Lane was extensively built on, as well as the neighborhoods of Charing Cross and Pall Mall. The New River was completed and many houses were supplied with water; sewers were dug; smooth pavements were laid down for passengers, and hackney coaches came into general use. But the streets were so narrow and dirty and the houses in so filthy a state that the city was scarcely ever exempt from the plague, which sometimes committed great ravages. In 1666 the great fire broke out and spread over 336 acres, destroying 13,200 houses, 90 churches, and many public buildings. In rebuilding, considerable improvements were introduced, and a fire in Southwark 10 years after gave a similar opportunity of improving that district. Population and trade now rapidly increased, partly from the immigration of French Protestants driven from their country by the revocation of the Edict of Nantes. In the 18th century London steadily advanced in extent, prosperity and splendor. In 1780 took place the Gordon riots, when the mob was in possession of London for two days and committed frightful havoc. Since that disgraceful outbreak the peace of London has never been seriously endangered, and the troops stationed in and around the capital, together with the effective police force that now exists seem quite adequate to ensure it against any similar disturbance. The extension and improvements which took place during the 19th century are greater than at any former period, and further changes of great importance are in operation. The most remarkable event of the century in the history of London was the carrying into effect in 1851 of the first great truly international industrial exhibition, which has since led to numerous exhibitions of a similar kind both there and abroad. In 1862 took place the second great international exhibition, and since that time various exhibitions of an international character and largely representing the colonies have been held in specially constructed buildings

at South Kensington. The history of London contains many episodes of vast importance to the nation as well as to London itself. As now united for government it will have to face problems of vast moment. The largest, most populous, and richest city that civilization has ever produced, the study of its history and its development must ever be of great importance and interest.

CHARLES LEONARD-STUART, B.A.,
Editorial Staff, 'Encyclopedia Americana.'

London, Ohio, village, county-seat of Madison County; on the Pittsburg, C. C. & St. L. and the Cleveland, C. C. & St. L. R.R.'s; about 26 miles southwest of Columbus and 65 miles northeast of Cincinnati. It is situated in an agricultural region and its industries are mostly connected with farm products. The manufactures are agricultural implements, lumber, shoes, and cigars. It is the trade centre for a large part of the county and ships considerable farm products and live-stock. The village owns and operates the electric-light plant. Pop. (1900) 3,511.

London, Ontario, Canada, a city and port of entry, the county-seat of Middlesex County, on the Thames River, and on the Grand Trunk, the Canadian Pacific, and the Lake Erie & D. R. R.R.'s, 105 miles west of Toronto. London is a noted summer and health resort, its white sulphur springs attracting many invalids. It was settled in 1826 and is distinguished by having river, bridges, streets, parks, and buildings named after the principal similar features of the great British metropolis. The city has electric street railways, electric and gas lighting, a good water supply and is the seat of Huron College, Hellmuth College, Hellmuth Ladies College, a normal school, collegiate institute, three libraries, orphan asylum and convent, several hospitals, and cathedrals of the Catholic and Anglican faiths. London is in one of the finest agricultural districts of the Dominion, and has numerous iron foundries, machine-shops, mills, chemical works, boot and shoe factories, tanneries, breweries, printing offices, and oil refineries, the factories in 1898 employing 6,000 people with an output of \$8,726,170. Population with London Junction and Ealing suburbs 45,000, of city (1901) 37,981.

London Clay, in geology and palaeontology, a formation of the Lower Eocene Age; so called from its existing at or near London, England. It consists of a tenacious brown and bluish-gray clay, with layers of concretions called septaria. It has a maximum thickness of 600 to 700 feet. Under the city the thickness of the clay varies with the valley of the Thames as affected by the erosion which formed it.

London, Treaties and Conventions of. The following are the most important of the treaties and conventions concluded in London in modern times: The Quadruple Alliance, formed 2 Aug. 1718. On 6 July 1827, a treaty

LONDON UNIVERSITY—LONDONDERRY

was signed between England, France, and Russia for regulating the affairs of Turkey and Greece, which led to the establishment of the Kingdom of Greece. On 22 April 1834, a quadruple alliance was formed between England, France, Spain, and Portugal against the claims of Don Carlos and Don Miguel to the crowns of Spain and Portugal. On 15 July 1840, a treaty was concluded between England, Russia, Austria, and Prussia to compel Mehemet Ali to restore Candia and Syria to the Porte; and on 27 November, at the conclusion of a short campaign by an Anglo-Austrian army in Syria, Mehemet Ali agreed to the terms of the treaty. A convention to close the Dardanelles against ships of war was signed on 13 July 1841; and a convention between France and England for suppression of the slave-trade, 29 May 1845. Austria, France, England, Prussia, Russia, and Sweden were parties to a treaty signed 8 May 1852, for settling the succession to the Danish crown, and guaranteeing the integrity of its dominions in relation to the duchies of Schleswig-Holstein. The rights of the German Confederation were reserved and the claims of the Duke of Augustenburg on the duchies relinquished on satisfaction. On 13 March 1871, at a conference of the great powers, the neutralization of the Black Sea, effected by the treaty of 1856, was abrogated. The neutralization of Luxembourg was guaranteed by the five powers at the conference of London, 11 May 1867. The Convention of London, which was concluded on 27 Feb. 1884, between the Transvaal and Great Britain, abrogated the Pretoria Convention of 3 Aug. 1881, and instead gave the Transvaal (thenceforward to be known as the South African Republic) independence in regard to its internal affairs, but reserved to the queen the right of veto over all treaties concluded "with any state or nation other than the Orange Free State," or "any native tribe to the eastward or the westward of the Republic."

London University, England, established as a joint-stock company in 1825, received in 1836 two charters, one for an association retaining the name of London University, and having power to examine candidates and grant degrees, and the other for a teaching body—the University College—entitling it to prepare students for the degrees conferred by the university. The object was to render academic honors accessible to all classes and denominations without distinction. The university became purely an examining body, granting degrees to all who passed the prescribed examinations, but not undertaking any teaching functions. An influential movement in favor of the establishment of a teaching university in the metropolis arose, however, and from 1888 commissions had the matter in hand, and in 1898 the London University Act was passed to give effect to their recommendations. A commission appointed to draw up statutes and regulations for the university in accordance with the act had its work formally ratified 29 June 1900, and the newly constituted university was established, the government granting the eastern and central portions of the Imperial Institute building to the university for its accommodation.

The eight faculties comprise arts, science, law, medicine, theology, music, engineering, and economics and political science, and the degrees

conferred are LL.D., LL.B., M.D., M.B., M.S., B.S., D.Sc., B.Sc., D.Lit., M.A., B.A., D.Mus., B.Mus. Candidates for any degree must first pass the matriculation examination, for which the subjects are Latin, English, mathematics, general elementary science, and one other subject selected from a prescribed list, including Greek, French, German, Sanskrit, Arabic, elementary mechanics, chemistry, sound, heat and light, magnetism and electricity and botany. For the ordinary degrees of B.A. and B.Sc. two other examinations must be taken. In the faculty of arts the highest degree is Doctor of Literature. Examinations are held at provincial centres as well as in London. The schools of the University, or institutions in which instruction is given, are: University College and King's College in all faculties; Hackney College, New College, Regent's Park College, Cheshunt College, Wesleyan College (Richmond), London College of Divinity in theology; Royal Holloway and Bedford Colleges in arts and science; the Royal College of Science; the South-Eastern Agricultural College, Wye; the medical schools of St. Bartholomew's, the London, St. Thomas's, St. George's, the Middlesex, St. Mary's, Charing Cross, and Westminster Hospitals, the London School of Medicine for Women; the Central Technical College of the City and Guilds Institute; and the London School of Economics and Political Science.

The supreme governing body is the Senate, consisting of the chancellor, 4 members appointed by the crown, 17 members elected by Convocation, 1 of them being the chairman of Convocation, 2 each elected by the Royal Colleges of Physicians and of Surgeons, 1 appointed by each of the four Inns of Court, and 2 by the Incorporated Law Society, 2 each chosen by University and King's Colleges, 1 representing the Corporation of London, 2 appointed by the London County Council, 1 representing the City and Guilds Institute, and 16 elected by the faculties. The Senate is debarred from imposing any religious test, or from imposing any disability on the ground of sex. There are three standing committees of the Senate, namely, the Academic Council, the Council for External Students, and a board to promote the extension of university teaching. The Chancellor, Vice-Chancellor, and Chairman of Convocation are *ex-officio* members of all three committees. Convocation consists of the Chancellor, the Vice-Chancellor, the members of the three standing committees, and the registered graduates of the university of prescribed standing. The parliamentary representative of the university is elected by the duly qualified male members of Convocation.

Lon'donderry, Charles William Stewart Vane, 3d MARQUIS OF, British military officer and diplomat: b. Dublin, Ireland, 18 May 1778; d. London 6 March 1854. He served under Sir John Moore and Sir A. Wellesley, in the Peninsula, distinguishing himself there at Talavera and other battles, and was English ambassador to Berlin in 1813. He was ambassador to Vienna the next year, and minister-plenipotentiary at its Congress in 1815. By his marriage with Miss Vane he succeeded to immense estates in the county of Durham, and devoted himself to their improvement and to the welfare of his tenantry. Under his original name of Stewart

LONDONDERRY—LONG

he wrote the 'History of the Peninsular War' (1808-13); 'Narrative of the War in Germany and France, 1813-4' (1830); and edited the 'Correspondence' of Viscount Castlereagh, his brother (1850).

Londonderry, Ireland, a city, seaport, county borough, and assize town, in the county of the same name, province of Ulster, on the Foyle, 23 miles from its mouth and 124 miles by rail north-northwest of Dublin. Waterside, a suburb on the opposite river bank, is united to the city by the iron Carlisle Bridge, 1,200 feet long. The houses of the town rise on the hill tier upon tier, while the summit is crowned by the cathedral. The ancient portion of the city is surrounded by a wall 1,708 yards long. It contains a small square, called the Diamond, from which four main streets diverge. The walls are pierced by seven gates, giving communication with other parts of the town, the greater part of which lies outside the walls. The most important public buildings are the guildhall, the county court-house, the post-office, the custom-house, the harbor offices, the jail, Gwyn's Institution, the model school, Magee College, Foyle College, St. Columb's College, the school of science and art, the lunatic asylum, and Ebrington Barracks. The harbor is commodious, and vessels of large tonnage can discharge at the quay, which extends for nearly two miles along the river, and is provided with a graving-dock. An extensive foreign, colonial, and coasting trade is carried on with English and Scotch ports, while Glasgow transatlantic steamers call three or four times a week at the mouth of the river. The principal export is agricultural produce; the chief imports are timber, grain, iron, coal, flax-seed, flour, and guano. Shirt factories employ thousands of workers, and there are timber-mills, grain-mills, foundries, coach-factories, bread and biscuit factories, distilleries, and a ship-building yard. Intermediate education is supplied by Foyle College, founded in 1617, and by St. Columb's Catholic College. Magee College opened in 1865, besides teaching secular subjects, has a theological course adapted to young men studying for the Presbyterian ministry. The Protestant cathedral is inferior to many parish churches in England. The Roman Catholic cathedral is a massive and magnificent structure, opened in 1873. The population is about equally divided into Roman Catholics and Protestants. Derry originated in a monastic establishment founded by St. Columba in the 6th century. It remained an ecclesiastical settlement until 1566, when it was occupied by the English in their wars with the O'Neills of Ulster. In 1608 the place was burned and the English governor slain by Sir Cahir O'Dogherty, one of the Irish chiefs of Donegal. During the 20 years that followed, the corporation of London, who obtained a grant of the place from James I., rebuilt the city, surrounded it with a wall, fortified it with cannon, and gave it a new name. Henceforth it was known as Londonderry. Here the Protestants of Ulster took refuge at the revolution, and held the fortress against the forces of James II., the siege lasting from April till August 1689; the defense by untrained men against superior numbers being regarded as one of the most heroic and successful military actions of modern times. Pop. (1901) 39,873.

Lone Star State, The, a name given to Texas from the device on its coat of arms: one star, or a "lone star" in the centre of a wreath.

Lone Wolf (GUIPAGO), Indian chieftain of the Kiowa tribe: d. 1870. He became head chief of his tribe in 1866. He refused to bring the tribe into a reservation, in accordance with the Medicine Lodge treaty, until compelled to do so by General Custer in 1869. However, he continued to maintain an attitude of defiance, and finally headed the hostile portion of his tribe in the southern outbreak of 1874. The outbreak was finally quelled by General Mackenzie; Lone Wolf, with the other chiefs, surrendered, and in 1875-8 was held prisoner at Fort Marion, Fla.

Long, Charles Chaillé, American soldier: b. Princess Anne, Somerset County, Md., 2 July 1842. He served in the Union army in the Civil War and attained the rank of captain. In 1869 he was appointed lieutenant-colonel in the Egyptian army; in 1874 was made chief of staff to General Gordon, and employed on a diplomatic and geographical mission to the interior of Africa. Returning in 1877 to the United States, he studied at the Columbia Law School, and was admitted to the bar. He was appointed consul-general in Korea in 1887. He is the author of: 'Central Africa' (1876); 'The Three Prophets — Chinese Gordon, the Mahdi, and Arabi Pasha' (1884).

Long, Crawford W., American physician: b. Danielsonville, Madison County, Ga., 1 Nov. 1815; d. Athens, Ga., 16 June 1878. He was graduated from Franklin College, Pa., in 1835, and from the Medical School of the University of Pennsylvania in 1839, and after practising a short time in Jefferson, Ga., removed to Athens, Ga., in 1851. He claimed to have performed on 30 March 1842 the first surgical operation ever made while the patient was unconscious from inhaling ether. This appears to have been done in accordance with careful reasoning upon the subject, but although he repeated the experiment successfully in three other cases not far from that time the facts did not then become generally known. In December 1844 Dr. Horace Wells in Boston demonstrated practically the principle of anaesthesia by the use of nitrous-oxide gas, and in 1846 W. T. G. Morton followed him in a similar discovery, and publicly demonstrated the feasibility of employing anaesthetics in surgical operations. In 1902 the Georgia Medical Association proposed to place a statue of Long in the National Capitol as the discoverer of anaesthesia. See ANAESTHESIA.

Long, Eli, American general: b. Woodford County, Ky., 16 June 1837; d. New York 1903. He was graduated from the military academy at Frankfort, Ky., in 1855, and received an appointment as 2d lieutenant in the 1st United States cavalry, serving in the Cheyenne expedition in 1857. During the Civil War he was in active service in the Federal army, was several times wounded, and was brevetted brigadier-general of volunteers in August 1864. He captured Selma, Ala., in April 1865. He was mustered out of the volunteer service in 1866 and retired as major-general. For many years previous to his death he had lived in Plainfield, N. J.

LONG—LONG ISLAND

Long, George, English classical scholar: b. Poulton, Lancashire, 1800; d. 10 Aug. 1879. He was educated at Cambridge and was professor of classical literature in the Brighton Proprietary College 1849–71. He was famous for his thorough knowledge of Latin and Greek literature. He published admirable translations of ‘Thoughts of the Emperor M. Aurelius Antoninus’ (1862–79) and ‘Discourses of Epictetus’ (1877); as well as editions of Cæsar, Sallust and Cicero.

Long, John Davis, American lawyer and politician: b. Buckfield, Oxford County, Maine, 27 Oct. 1838. He was graduated from Harvard in 1857; taught in Westford Academy for two years; then studied law at Harvard law school and was admitted to the bar in 1861. He built up a large practice and became senior member of his firm, Long & Hemenway. He has been an active member of the Republican party; served in the Massachusetts legislature 1875–8, being speaker of the House from 1876–8, and was elected lieutenant-governor of the State in 1879; the next year he was elected governor, and re-elected in 1881. He was also for several years on the state house construction commission of the State. In 1883 he was elected to Congress, serving there till 1889; he was then a candidate for the Senate but was defeated, and did not hold public office till appointed secretary of the navy by President McKinley in 1897. He held this office through the Spanish War, conducting its affairs with marked ability, and resigned in March 1902. He published in 1879 a translation of the ‘Æneid’ of Virgil.

Long, Stephen Harriman, American engineer: b. Hopkinton, N. H., 30 Dec. 1784; d. Alton, Ill., 4 Sept. 1864. He was graduated at Dartmouth College in 1809, and after teaching school entered the United States engineer corps in 1814. He taught mathematics at West Point 1814–16, and was subsequently engaged for several years in surveys of the country west of the Mississippi River, as well as of the Upper Mississippi. Long’s Peak in the Rocky Mountains was named in his honor. When the construction of the Baltimore & Ohio railroad was commenced in 1827 Long became chief engineer of surveys and introduced many improvements in wooden bridges, to adapt them for railroad purposes. In the construction of railroads he established a system of curves in locating roads. He served for some years on the board for the improvement of the Mississippi, and in 1856 was placed in charge of that work. He was appointed colonel of engineers in 1863, retiring the same year.

Long, William Joseph, American Congregational clergyman and author: b. North Attleboro, Mass., 3 April 1867. He was graduated from Harvard in 1892 and from the Andover Theological Seminary in 1895. He is the author of: ‘The Making of Zimri Bunker’ (1898); ‘Ways of Wood Folk’ (1899); ‘Wilderness Ways’ (1900); ‘Beasts of the Field’ (1901); ‘Fowls of the Air’ (1901); ‘Secrets of the Woods’ (1901); ‘School of the Woods’ (1902); ‘Following the Deer’ (1903); ‘A Little Brother to the Bear’ (1903).

Long Branch, N. J., city, in Monmouth County; on the Atlantic Ocean, and on the

Pennsylvania, the New Jersey S., and the Central of New Jersey R.R.’s; about 35 miles by water, 45 miles by rail, and 30 miles in direct line south of New York city. During the summer season steamers run regularly several times a day between New York and Long Branch, and electric lines connect the nearby cities and towns with this famous summer resort. Long Branch is made up of large hotels, boarding houses, cottages, bathing houses, parks, stores, and places of amusement. It is well prepared to take care of the thousands of people who visit the place in the hot summer months. It has 16 churches, the Star of the Sea Academy, public schools, the Monmouth Memorial Hospital, a circulating library, and public reading rooms. The avenue along the bluff is a favorite walk. The long beach affords excellent bathing facilities. Large bulkheads have been erected to prevent destructions of the bluff by the action of the waves. The government is vested in a commission composed of seven members, who choose the mayor from among the number. Four of the commissioners are elected by wards, three at large, and all are elected annually. There are three banks with a combined capital of \$200,000.

Long Branch is one of the oldest summer resorts in the United States. As early as 1670 settlements had been made along the coast. Colonel White of the British army, who owned the land where Long Branch is located and in the vicinity, about 1770, used to spend his summer months at this place. After the Revolution people from Philadelphia began to visit the place during the hot months, and in the last of the 18th century it had quite a reputation as a summer resort. Prior to its occupancy during the summer by people from New York and Philadelphia, it was frequented by fishermen and wreckers. Its proximity to New York, Philadelphia, and other cities gives it a large number of guests during the season. Pop. (1900) 8,872.

CHAS. L. EDMONDS,
Editor of Long Branch ‘Record.’

Long Island, New York, the southeastern-most portion of the State, connected by three bridges and several ferries across East River with Manhattan Island; is bounded on the north by Long Island Sound (q.v.), separating it mainly from the south shore of Connecticut. The Atlantic Ocean bounds it on the east and south, while The Narrows, New York Bay, and East River, already mentioned, connecting the ocean with the Sound, complete the boundaries on the west and northwest. Several small islands around the coasts are included in its political boundaries, the best known being Coney, Rikers, Berrian, South Brother, Fire, Barren, Shelter, Gardiner, Fisher, and Plum. Long Island has a maximum length of about 120 miles, varies in width from 12 to 23 miles, and has an area of 1682 square miles. It is divided into four counties, Nassau, Suffolk, Queens, and Kings, the last two metropolitan boroughs of New York city, occupying a considerable portion of the western end of the island. Queens County embraces the populous centres of Long Island City (q.v.), Maspeth, Corona, Flushing, Jamaica, Woodhaven, and Far Rockaway, while the boundaries of Kings County are those also of the former city, now the metropolitan borough, of Brooklyn (q.v.).

LONG ISLAND

The 280 miles of coast line are indented with numerous bays and inlets. A deep bay, 30 miles long, divided into Great and Little Peconic, and Gardiner's bays, splits the eastern end of the island into two long narrow peninsulas, the southern terminating at Montauk Point, and the northern at Orient Point, with Plum and Fishers islands extending beyond. Great South Bay, from two to five miles broad, extends along the southern coast for nearly half the length; it is separated from the Atlantic Ocean by Fire Island or Great South Beach, a sandy strip from a quarter of a mile to one mile wide, communicating with the ocean by several openings. Jamaica Bay is on the south coast also, New York Bay on the west, while along the north coast are Flushing, Little Neck, Manhasset, Hempstead, Oyster, Huntington and Smithtown bays. A government system of lighthouses, life-saving stations, fortifications, and masked batteries extends around the coast.

The level seacoast of the south side, with its extended views of bay and the broad ocean, contrasts sharply with the hilly north side and its deep indentations, looking out upon the land-locked Sound. The rolling stretches of Montauk Point and Shelter Island afford another contrast to the many square miles of scrub oak and level sandy plains in the centre of the island. The island reaches a height of over 380 feet in West Hill, Suffolk County, and in Harbor Hill at Roslyn, the loftiest points in the range of glacial hills that extends along the northern coast. The island is well watered by several small streams, the Peconic, 15 miles long, flowing into Great Peconic Bay, being the largest. Natural ponds or lakes abound, and there are about 116 square miles of salt marsh throughout the island. The eastern portion especially is well wooded and noted for its pine forests well stocked with deer and other game. Like other insular positions the climate is milder than that of the adjacent continent, the average temperature being several degrees below that of the metropolis, while the hottest days are tempered by cool and refreshing breezes from ocean or Sound. The soil generally is productive and under a high state of cultivation. In the southern flat lands it is of a light, sandy nature, well calculated for raising grain, especially Indian corn; in the hilly north the soil is strong and adapted to the culture of grain, hay, and fruits. Market gardening for metropolitan demands constitutes the principal portion of the agricultural industry of Kings and Queens counties. Oyster, clam, and other fisheries are important sources of food supply.

The Long Island and other railroads give easy access from New York city to the remotest parts, Montauk Point, the southeasternmost point, being only three hours away. Long Island is noted especially for exceptional opportunities, embracing all sorts of summer recreation. The roadways are admirably adapted to all forms of locomotion, and riding, driving, automobiling, and wheeling, are equally desirable methods for enjoying the region. In the numerous villages and towns along Jamaica Bay, Great South Bay, Peconic Bay and the Sound there are ample facilities for sailing, rowing, fishing, and bathing, which are fully utilized. For golfing, lawn tennis, and all other forms of outdoor sport and recreation, every possible fa-

cility is found, and the golf courses, especially at Garden City and Shinnecock, are notable. The chief seaside resorts along the south coast are Bath Beach, Bensonhurst, Coney Island, Brighton, Manhattan, Rockaway Beach, Far Rockaway, Long Beach, Fire Island, Patchogue, and Montauk Point; along the north coast are Greenport, Port Jefferson, Coldspring Harbor, Oyster Bay, Glen Cove, Seaciff, College Point and North Beach. The population of Long Island in 1900 was 1,452,611, 1,166,582 of this number residing in Brooklyn borough.

When discovered in 1609 by Hudson, Long Island was inhabited by 13 tribes of Algonquin Indians, by whom the island was variously called Panmancke, Wamponomon, Mautowacks, and Sewanlackey. A few descendants mixed with negro blood, and retaining no knowledge of their ancient language, dwell near Montauk Point and Shinnecock Neck. French Protestants from near the river Waal, in the Netherlands, made the first settlement in 1625 under Dutch protection, and immigrants from New England established themselves in different localities shortly afterward. Lange Eylan, the Dutch name, was changed by the colonial legislature to that of Nassau, a name which survives in one of the counties, but was never adopted by the people for the island. Long Island was a busy base of military movements during the Revolutionary War, and the Battle of Long Island (q.v.) is the principal event in its history.

Long Island, Battle of, one of the early American defeats in the Revolutionary War, was fought 27 Aug. 1776, in Brooklyn, N. Y., mainly within the present limits of Prospect Park, the column in Battle Pass to the memory of the 400 Maryland troops who fell in the battle, and the foundation remains of the redoubt on Lookout Hill, marking the central point of defense and attack. After the evacuation of Boston by the British, Washington made strenuous efforts to fortify New York and its approaches. General Greene, in command of a considerable body of troops, mostly raw recruits, was entrusted with the defense of Long Island, and constructed a line of intrenchments and redoubts from Wallabout Bay to Gowanus Cove. The main works at the Wallabout end were on the hill afterward known as Fort Greene, now marked by Washington Park. At Gowanus Cove, a battery was erected at Red Hook, and a fort on Governor's Island, nearly opposite. About two and a half miles from the intrenchments, between them and the southwest side of the island, the range of low hills in this section was then densely wooded and crossed by three roads; one on the right of the works passing near the Narrows to Gravesend Bay, the central one through Flatbush, and the third far to the left through Bedford to Jamaica. In the midst of his preparations, General Greene fell ill, and the command devolved upon General Sullivan, then just returned from Lake Champlain. Unacquainted with the ground and with Greene's plans the change of command caused considerable confusion. Nine thousand British troops landed in Gravesend Bay on 22 August without resistance; they were commanded by Sir Henry Clinton, assisted by Lords Cornwallis and Percy, General Grant and Sir William Erskine. Lord Cornwallis, rapidly advancing to the central pass, found it occupied by the rifle regiment of Colonel Hand, and without risking

LONG ISLAND CITY — LONG PARLIAMENT

an encounter, took up a position at Flatbush. Washington inspected the American lines on the 24th, and placed General Putnam in command. The following day the British were reinforced by two brigades of Hessian troops, under General De Heister, and on the 26th began to carry out their plan of operations. The road through Bedford to Jamaica unfortunately had been comparatively neglected by the Americans, and eluding the patrol, the British contingent under General Clinton, accompanied by General Howe, the commander-in-chief, and by Lords Percy and Cornwallis, guided by a local tory, gained possession of the road and neighboring heights undiscovered during the night of 26-7 August. In the morning, General Grant, with the left wing of the British army, advanced along the road by Gravesend and the Narrows, and was resisted by Colonel Atlee with a guard of Pennsylvania and New York militia, who retired fighting until he had fallen back upon General William Alexander (Lord Stirling), whose two regiments had hastened to his assistance. Here active firing was kept up by both sides without an attempt at a general action. At the same time, as diversions, De Heister opened up a cannonade from Flatbush upon Colonel Hand and his riflemen, while the guns of the British war-vessels were trained upon the Red Hook battery. Meanwhile on the right Clinton opened his guns upon the Americans, and at this signal De Heister advanced to storm the central pass and the redoubt of which General Sullivan had taken command. The latter, who found his left flank engaged and himself in danger of being surrounded, ordered a retreat, but not soon enough to escape the British light infantry, who drove him back upon De Heister and his Hessians. The Americans fought with desperate valor, a large body cutting their way through the intrenchments, the rest who were not killed either escaping among the hills or surrendering as prisoners, among the latter being General Sullivan. On the left Colonel Atlee and Lord Stirling, who had maintained their position in front of General Grant, found themselves cut off by Cornwallis. They gallantly attacked the enemy with such determination that the British held their ground only by the assistance of reinforcements, when Stirling seeing the uselessness of further resistance surrendered. Having forced all the approaches the British proceeded to invest the American works.

Washington arrived in the evening and took command, the following day bringing over additional troops. But with the formidable British force opposed to him, and indications that the British fleet intended moving up the river so as to cut the force in Brooklyn entirely off, Washington, on the night of 29-30, favored by a thick mist, made a strategic and masterly retreat to Manhattan, greatly to the discomfiture of the British, who were unaware of the movement until some time after the last American had crossed in safety. The Americans lost over 900 men in the battle, while the British loss in killed wounded and missing was 400. Consult: Carrington, 'Battles of the American Revolution' (1876); Dawson, 'Battles of the United States' (1858); Field, 'Battle of Long Island' (1869).

Long Island City, N. Y., formerly a city in Queens County, and second in size on Long Island, now in the borough of Queens, in New

York city. It became a part of New York 1 Jan. 1898. As early as 1640 Dutch settlers had taken possession of the land in this vicinity, and gradually a number of little villages were formed on the western end of the island, on the East River and the Sound. In 1870 a number of the little villages, Astoria, Blissville, Dutch Kills, Hunter's Point, Middletown, Ravenswood, and Steinway, were united into one municipality and called Long Island City. Newtown Creek separates this section from the borough of Brooklyn. Ferries connect it with the borough of Manhattan. It has extensive manufacturing interests, several hospitals, a large number of churches, and schools. Consult: Kelsey, 'History of Long Island City.'

Long Island Sound, a body of water which separates Long Island, in New York State, from the mainland. It is an arm of the Atlantic Ocean, extending northeast and southwest; about 110 miles long and from 10 to 25 miles wide. It is connected with the Atlantic on the east by The Race, a narrow passage south of Fishers Island; and on the west by a strait called the East River, which enters New York Bay and through the Narrows to the ocean. The coast on the north is irregular, and has a number of small bays and capes. The south or Long Island coast is irregular from East River to near Port Jefferson; and from Port Jefferson to Orient Point the coast line has few indentations. The largest indentations on the north side are New Haven Harbor and Pelham Bay. There are several good harbors at the mouths of rivers and in places sheltered by small islands. On the south shore the principal indentations are Smithtown, Northport, Oyster, Manhasset, Little Neck, and Flushing bays. The north coast is fringed by small rocky islands or reefs. In the western part of the Sound there are a number of small islands, which have been improved so as to be desirable resorts or residential locations. Chief among these are Glen Island and City Island. At the entrance to East River there are a number of islands used chiefly by the health department of New York city. At the east entrance is a group of islands which extend diagonally from Long Island to the State of Rhode Island. The largest of this group is Fishers Island. (See NEW YORK CITY.) The chief rivers which flow into the Sound, all from the north, are Connecticut, Mystic, Thames, and Housatonic.

Since the improvements made (1865) at Hell Gate (q.v.), Long Island Sound is an available route for ocean steamers. The large passenger steamers which ply daily between New York and New England ports pass through the Sound. A large number of forts with modern equipment are located along the shores, thus guarding most carefully the entrance to New York city by this route.

Long Parliament, in English history, a Parliament summoned by Charles I. in 1640. Largely liberal and anti-royal, thanks to the campaigning efforts of John Pym, it declared ship-money illegal, claimed the right of taxation as belonging solely to the Commons and not to the Crown, passed the Triennial Bill, and, attacking the King's favorites put Laud in prison and Strafford to death. In November 1641, passing successfully a reactionary crisis, it adopted the Great Remonstrance, and in January

LONG-TAILED DUCK—LONGEVITY

of the next year refused to obey the king's order to surrender "the five members," its leaders, Hampden, Pym, Hollis, Haselrigg and Strode. Thus it brought on the Civil War, through which it continued in power, losing however many members upon the introduction of Presbyterianism, and nearly 100 Presbyterians in 1648 after its attempted compromise with the king, which aroused the anger of the Parliamentary army. The handful of members left composed the "Rump," which was nominally in power until dissolved in 1653 by Cromwell, after whose death it briefly reconvened in 1659 and 1660. See CROMWELL.

Long-tailed Duck. See OLD SQUAW.

Long Tom. (1) the name given a 42-pound gun captured by the British in 1798 from the French battleship Hoche. It was afterward purchased by the Americans and used in the attack on Haiti by the French in 1804, and remained idle till 1812, when it was placed on the General Armstrong. This vessel ran the British blockade at New Orleans 9 Sept. 1814, and put into the bay near Horta, Fayal, being disabled in an encounter with a British squadron. Here the gun was dismantled and remained till Colonel Reid, son of the commander of the General Armstrong, had it brought back to New York 18 April 1893. (2) An apparatus for washing gold from the earth or gravel in which it is found. It consists of a wooden trough, from 12 to 25 feet long and about a foot wide. At its lower end it widens, and its floor there is of sheet-iron pierced with holes half an inch in diameter, under which is placed a flat box a couple of inches deep. A stream of water is kept running through it by means of a hose; the dirt is shoveled in, and stirred at the lower end, where the earth and gravel fall through the sieve into another box, where they are again sifted. The machine, like the "rocker," was cheap and wasteful; and both were soon displaced by the sluice.

Long'acre, James Barton, American engraver: b. Delaware County, Pa., 11 Aug. 1794; d. Philadelphia 1 Jan. 1869. He was apprenticed in Philadelphia, and in 1819-31 was employed in the illustration of many of the foremost American works then published. At first with James Herring, and later independently, he published the "National Portrait Gallery of Distinguished Americans" (1834-9), many of whose engravings were from sketches by himself. In 1844 he was appointed engraver to the United States mint, and from that time until his death designed all new coins. He also remodeled the coinage of Chile.

Lon'gan, a tree and its fruit. See LITCHI.

Longard de Longgarde, Dorothea. See GERARD DOROTHEA.

Longchamps, lōn-shōn, Paris, France, a celebrated racecourse on the southwest side of the Bois de Boulogne, where the race for the "Grand Prix" is run. Prior to its suppression in 1792, part of the site was occupied by the Convent of Longchamps, founded in 1260, a not too rigid retreat for ladies of the higher classes. It was a popular resort for carriage driving, especially during the week preceding Easter.

Longe, a local name (Vermont) for the lake trout (q.v.).

Longevity, lōn-jēv'i-ti. The duration of life varies greatly in the same group of plants and animals, and great age in animals is by no means confined to the few higher vertebrates, such as the elephant, crocodile or parrot. Even so lowly an organism as the sea-anemone has been kept alive for 55 years. Low herbaceous annual plants in the temperate zone, have co-species in the tropics which grow to be trees and are perennial. Not only are individuals of a species long-lived, but certain species and genera exhibit wonderful vitality and have persisted throughout many geological ages, such are *Lingulella*, *Limulus*, *Ceratodus*, and certain foraminifers which have persisted since the Silurian period.

Causes of Longevity.—They have to do with the nature of the physical surroundings, and also depend on slow growth and late reproduction. Botanists find that great age in plants is dependent on slow growth, gradual propagation carried on late in life, on the solidity and hardness of the tissues, etc. Examples of great age in plants are the Sequoias or "big trees" of California, which are supposed to be over 3,000 years old; in fact, they are survivors of Tertiary times, since they occur in a fossil state in the polar regions in British Columbia and in Europe.

The longevity of certain species of animals has been attributed by Weismann to favorable environment, including temperature. He considers that the duration of life depends first upon the length of time which is required for the animal to mature, and upon the length of the period of fertility, the latter point being determined by external conditions. Undoubtedly another factor is heredity, since longevity is directly transmissible from parent to offspring, and great age runs in families.

As to longevity in the lower animals little is known. As a rule, they live but a few weeks, months, or years. The crayfish is said to attain an age of 20 years, and possibly the lobster may live to be as old as that. Lampreys preserved in Roman fishponds are said to have lived to be nearly 60. The crocodile, which never stops growing through life, lives 100 years. Pike and carp reach the age of 150 years. A gigantic salamander of Japan lived at least 52 years in confinement in Germany. As to the age of birds a writer in the British ornithological journal "Ibis," states that the following records of birds in captivity are authentic: raven 50, gray parrot 40 and 50, blue macaw 64, eagle-owls 53, and one was then still alive at 68 years. Certain aquatic birds are very long-lived, as a heron of 60, goose 80, mute swan 70. A goose still living in Rhode Island in 1903 is known to be 50 years of age. To what age in free nature these birds may reach is unknown. The elephant is known to live a century and the whale is supposed to be equally long-lived. The horse rarely reaches the age of 40, though according to Lawrence "Old Billy" of Manchester was known to have lived 59 years, and died at the age of 61, while Albertus, an old veterinarian, writes that he knew a soldier actually serving upon a horse which was 70 years of age.

Man sometimes reaches the age of 100 years, and in rare instances even exceeds that age; while heredity undoubtedly has most to do with great age, it may be promoted in those of medium height by quiet, regular habits, moderation in eating and abstention from or moderation in

LONGFELLOW

the use of stimulants and tobacco. Women attain a greater age than men. To show that in man the mean duration of life may be extended by good sanitation and improvement in the general conditions of life, the mean duration of life in France has risen from 29 years at the close of the 18th century to 40 years. The United States census report for 1900 on deaths that occurred in 271 cities of 5,000 population or more shows that 18.6 persons died in 1900 out of every 1,000, whereas in 1890 the number who died in the same cities was 21 out of every 1,000. The average age at death in 1890 was 31.1 years; in 1900 it was 35.2 years. If these statistics be accurate the saving of human life that has been achieved in a decade is enormous. Consult: Weismann, 'Essays upon Heredity, etc.' (Oxford 1889); Lankester, 'On Comparative Longevity in Man and the Lower Animals' (London 1870); Lolaville, 'The Duration of Human Life,' in the 'Popular Science Monthly,' Vol. XX., November 1881.

Longfellow, Ernest Wadsworth, American artist: b. Cambridge, Mass., 1845. He studied under Couture in Paris, and among paintings by him may be named: 'Italian Pines'; 'Misty Morning'; 'John and Priscilla'; 'Old Mill at Manchester'; and a portrait of his father, Henry W. Longfellow, the poet.

Longfellow, Henry Wadsworth, American poet: b. Portland, Maine, 27 Feb. 1807; d. Cambridge, Mass., 24 March 1882. His father, Stephen Longfellow, was a prominent and cultured lawyer of Portland, having graduated from Harvard College, with Dr. Channing and Joseph Story, in 1798. He married Zilpah Wadsworth, daughter of Gen. Peleg Wadsworth, who fought in the Revolution, in 1804. The poet's mother was singularly imaginative and sympathetic, and fond of poetry and music. Henry was the second of four sons and of eight children. At 15 he entered the sophomore class at Bowdoin College, and discovered much taste for literature, and unusual facility in verse. After his graduation in 1825, he was selected as the most promising candidate for the newly established professorship of modern languages at Bowdoin, and was sent to Europe to prepare for the work. He traveled and studied in France, Spain, Italy, and Germany, and acquired considerable linguistic knowledge in the three years of his stay. In 1829 he returned and took up his duties, which were onerous, involving the preparation of elementary text-books in French and Spanish. In 1831 he married Mary Storer Potter, daughter of Judge Barrett Potter, and a schoolmate of earlier years. He wrote for the 'North American Review,' and began to contribute to the 'New England Magazine' some of the papers from the 'Sketch Book of Scenes in France, Spain, and Italy,' which he had prepared abroad. These were collected and issued as the two parts of 'Outre-Mer' in 1835. Two years earlier he had published his translation of 'Coplas de Manrique,' prefaced by his article from the 'North American Review' on 'The Moral and Religious Poetry of Spain.' This little book attracted the attention of George Ticknor, then about to resign the professorship of modern languages in Harvard College, and seems to have had much to do with making its author his successor. The position was tendered

and accepted, and Longfellow sailed, accompanied by his wife, in the spring of 1835, for a year of further study abroad. By way of London, where they met the Carlyles and other literary people of note, they went to Copenhagen and Stockholm, for study of the Scandinavian languages, which detained them till the close of the year. In December, on their way to the south, Mrs. Longfellow died at Rotterdam. Longfellow spent the winter and spring at Heidelberg, finishing the year in Switzerland and the Tyrol. He began his work at Cambridge in December 1836, taking lodgings at Cragie House, where Washington had his headquarters in the first year of the Revolution. In 1839 appeared 'Hyperion,' containing, in a somewhat sentimental vein, the cherished thoughts and impressions of his stay in the Tyrol and Switzerland, and also 'Voices of the Night,' his first volume of verse. The latter work was conspicuously successful, and did much to strengthen the influences that were drawing him away from teaching and from prose tasks. After two years of further service, he was forced, by the state of his health, to ask for a leave of absence, and in the spring of 1842 sailed again for Europe, returning somewhat benefited late in the year. He employed his time, during the return voyage, upon a series of 'Poems on Slavery,' which was at once published, and led to some unkindly criticism. In 1843 Longfellow married Frances Elizabeth Appleton, daughter of Nathan Appleton, a Boston merchant. This year he published 'The Spanish Student,' a drama in three acts, and in 1845 his 'Poets and Poetry of Europe,' as also, in 1846, 'The Belfry of Bruges, and other Poems.' This was followed in 1847, on a theme suggested by Hawthorne, by the famous 'Evangeline.' Two years later he produced 'Kavanagh,' a somewhat artificial story of New England life, and in 1850 'The Seaside and the Fireside,' which was followed the next year by 'The Golden Legend.' In 1854 Longfellow gave up the cares of his professorship, that he might write, and at once began serious work upon his long-delayed translation of Dante, and on an Indian poem that he had not yet named. This latter, eventually called 'Hiawatha,' was finished near the close of the year. In 1858 appeared 'The Courtship of Miles Standish,' which showed increased skill in the handling of hexameters, and was very favorably received. In July 1861 Mrs. Longfellow died from injuries caused by the burning of her gown, ignited by a dropped match. After two years, 'Tales of a Wayside Inn' appeared, and in 1867 'Flower-de-Luce,' and the first part of 'Dante's Divine Comedy.' This translation was fully published in 1870. In 1868 'The New England Tragedies' was finished. This year, with a family party, Longfellow sailed for England, receiving everywhere the honors of the country, and in special the degrees of LL.D. from Cambridge and D.C.L. from Oxford. The party traveled through Switzerland to Italy, returning to America by way of Scotland in September of the next year. Longfellow began work again industriously, bringing out 'The Divine Tragedy' in 1871, and 'Christus,' and 'Three Books of Song' in 1872. In 1874 appeared 'Aftermath,' and the year after 'The Masque of Pandora and other Poems.' In 1876 was published the first number

LONGFELLOW—LONGINUS

of 'Poems of Places,' which ran up to 31 eighteenmo volumes, and occupied three years in the editing. He had twice essayed similar collections, 'The Waif' (1845), and 'The Estray' (1846), many years before. In 1878 he published 'Kéramos, and other Poems,' and in 1880, 'Ultima Thule.' In October of 1881 he was seized with vertigo, followed by nervous prostration, which stopped all further work, and in March of the next year he succumbed to an attack of peritonitis of less than a week's duration. He was a man of an impressionable and sprightly nature, and of great sweetness and purity of life, knowing neither enemies nor rivals. His genius was essentially lyrical, and his refined facility in literature gave him his capital rather than his powers of analysis and of thought. He is the first of American and perhaps of modern English poets in popularity and a hundred translations from his work have been made in eighteen leading languages of the world. Consult: S. Longfellow, 'Life of Henry W. Longfellow' (1886); and 'Final Memorials of Henry W. Longfellow' (1887); Robertson, 'Longfellow' (1887); Wendell, 'Literary History of America' (1900); Carpenter, 'Henry Wadsworth Longfellow' (1901); Higginson, 'Longfellow' in 'American Men of Letters' series (1902).

L. A. SHERMAN,
Of the University of Nebraska.

Longfellow, Samuel, American Unitarian clergyman and poet: b. Portland, Maine, 18 June 1819; d. Cape Elizabeth, Maine, 3 Oct. 1892. He was a younger brother of H. W. Longfellow, and was graduated from Harvard in 1839 and from Harvard Divinity School in 1846. After his ordination to the ministry he was pastor of the Unitarian Church at Fall River, Mass., 1848-51; of the 2d Unitarian Church in Brooklyn, L. I., 1853-60; and of the Unitarian Church at Germantown, Philadelphia, 1877-82. His remaining years were spent in Cambridge. His fame as a poet has been overshadowed by that of his brother, but he had a very distinct poetic gift, and his hymns, of which he wrote many, are among the best of modern religious lyrics and are found in hymnals of many denominations. He possessed a gentle, unaggressive nature, but held his convictions firmly, nevertheless, and was fearless in the expression of his religious and poetical opinions, his views being more often radical than conservative. His published works include: 'A Book of Hymns,' with S. Johnson (1846), a compilation revised in 1864 as 'Hymns of the Spirit'; 'Thalatta: a Book for the Seaside,' with T. W. Higginson (1853), a verse compilation partly original; 'Life of Henry Wadsworth Longfellow' (1880); 'Final Memorials of Henry Wadsworth Longfellow' (1887); 'Essays and Sermons' (1894); 'Hymns and Verses' (1894). Consult: May, 'Memoir and Letters of Samuel Longfellow' (1894).

Longfellow, William Pitt Preble, American architect: b. Portland, Maine, 25 Oct. 1836. He is a nephew of Henry W. Longfellow (q.v.), and was graduated from Harvard in 1855. He was assistant architect of the Treasury Department 1869-72; is a fellow of the American Society of Architects, and was the original editor of 'The American Architect.' He was chairman of the architectural section of

the Board of Judges of the World's Columbian Exposition, 1893. He has published: 'Abstract of Letters on Perspective' (1889); 'Cyclopedia of Architecture in Italy, Greece and the Levant' (1895), a work of great value; 'The Column and the Arch' (1899); 'Architectural Essays.'

Long'fin, a large and important sea-fish (*Chilodactylus macropterus*) about the Cape of Good Hope. It represents a family, having several other food-fishes of value in the Indian Ocean and Australian seas, all characterized by elongation of one of the rays of each pectoral fin.

Longhena, Baldassare, bäl-däs-sä'rä löng'na, Italian architect: b. Venice about 1604; d. there 1682. He carried to its highest pitch the Venetian baroque, in which he followed to some extent his predecessors Palladio and Scamozzi. In the plastic accessories of his buildings he was far less original. He built in 1631-56 the great church of Santa Maria della Salute (commonly called "The Salute"), an octagonal structure with two domes. The churches of Santa Giustina, San Tomà, and Santa Maria ai Scalzi; the Palazzo Rezzonico and the staircase of the cloister of San Giorgio Maggiore were also his work.

Longhi, Giuseppe, joo-sép'pé löng'gē, Italian engraver and painter: b. Monza 13 Oct. 1766; d. Milan 2 Jan. 1831. He studied line-engraving in the school of Vangelisti at Milan, was for a time at Rome, but later established himself at Milan, where he was a professor in the Academy from 1798. He was unexcelled among contemporary engravers in excellence of portraiture. Among his plates are: 'Bonaparte' after Gros; 'The Philosopher' after Rembrandt; 'The Vision of Ezekiel' after Raphael; 'Washington' after Stuart; 'Eugène Beauharnais' after Gérard; and 'The Emperor Franz I.' after Schiavoni. He published 'Teoria della Calcografia' (1830), once well known.

Longicornes, lön-jí-kör'nëz, or **Long-horned Beetles**. See CERAMBYCIDÆ.

Longino, Andrew Houston, American lawyer: b. Lawrence County, Miss., 16 May 1855. He was graduated from Mississippi College, Clinton, Miss., in 1876 and until 1880 was clerk of the circuit and chancery courts for Lawrence County. He was elected to the State senate in 1880 and in the following year was admitted to the bar. He served until 1884 in the State senate and was appointed district attorney for southern Mississippi and in 1894 became chancellor. He was elected governor of Mississippi for a term of four years in 1900.

Longinus, Cassius, Athenian Neoplatonic philosopher and rhetorician: b. about 213 A.D.; d. Palmyra, Syria, 273 A.D. Greek literature was the principal subject of his studies. He studied the philosophy of the day under Ammonius Saccas at Alexandria, but subsequently became an ardent adherent of the Platonic philosophy, and annually celebrated the birthday of its founder by a banquet. He afterward visited the East, and on the invitation of Queen Zenobia went to Palmyra to instruct her in Greek learning and to educate her children. On the death of her husband he was employed by her in the administration of the state, and advised her to throw off the Roman yoke, by which means he was involved in the fate of this queen. For

LONGITUDE — LONGSPURS

when Zenobia was taken prisoner by the Emperor Aurelian, and could save her life only by betraying her counsellors, Longinus, as the chief of them, was seized and beheaded 273 A.D. He suffered death with all the firmness of a philosopher. He was distinguished by his oratory as well as his statesmanship and love of liberty. He appears to have known Latin and Syriac as well as Greek. The work known as 'Longinus on the Sublime,' the best piece of literary criticism in the Greek language, was written either by him or by a certain Dionysius Longinus, whose date is the 1st century after Christ.

Longitude, lön'jē-tüd, of a heavenly body, is the angle between two planes, both of which are at right angles to the ecliptic, and pass through the sun (heliocentric longitude), or through the earth (geocentric longitude). The longitude of a place on the earth is the angle between the meridian through the place and some fixed meridian. At the Geodetic Congress held in 1884 at Washington, and composed of scientific representatives from the principal countries of the world, it was resolved to adopt the meridian of Greenwich as the universal prime or first meridian, the representatives of France being the only important objectors. Longitude, or the angle between two meridians, may be measured by the arc of the equator, or of any parallel intercepted between them. As the parallels get smaller toward the poles, it is evident that degrees of longitude which are $69\frac{1}{2}$ statute miles long at the equator get shorter toward the poles. At all places of the same latitude the length of a longitude degree (measured due east and west) is the same. All methods of determining longitude are based on this fact: (1) A method formerly employed to determine the difference in longitude between two land stations was to carry chronometers backward and forward a number of times from one place to the other until the effects of variation of rate had been eliminated; comparison of their indications with the sidereal times at the places gave the longitude. (2) A ship carries a chronometer indicating Greenwich time; the local time at any place is known from observation of the sun, hence the longitude of the place may be calculated. (3) The Nautical Almanac gives the Greenwich time at which the moon is at certain distances from certain stars; mariners note the local time at which the moon is at the same distances from these stars (they are aware of the local time from observation of the sun in the daytime), and so the longitude is known. (4) The eclipses of Jupiter's satellites are seen by all observers on the earth at the same instant; their Greenwich times being noted in the Nautical Almanac, and their local times being observed as in method (3), the difference in time from Greenwich is known. The tables of these eclipses are not yet complete enough for this method to be in great use. Observations of lunar transits and the occultation of fixed stars afford other means of determining longitude. See also LATITUDE.

Longley, James Wilberforce, Canadian politician: b. Paradise, Nova Scotia, 4 Jan. 1849. He was educated at Acadia College, N. S., studied law in Halifax and was called to the bar in 1875, becoming Queen's Counsel in 1890. He was chief editorial writer for the 'Acadian Re-

corder' 1873-87, and was managing editor of the Halifax *Morning Chronicle* (1887-91). Since 1882 he has been a member of Nova Scotia Assembly and in 1886 was made attorney-general. He materially assisted the passage of the bill for the abolition of imprisonment for debt.

Long'mans, London publishers for many years identified with high-class literature. Thomas Longman (1699-1755) was apprenticed to John Osborne, bookseller, Lombard Street. Longman bought the business of William Taylor, publisher of 'Robinson Crusoe,' conducted in Paternoster Row, whence he moved in 1726 to the present site. Longman was a shareholder in many important publications, such as Boyle's 'Works,' Ainsworth's 'Latin Dictionary,' Chambers' 'Cyclopedia,' and Johnson's 'Dictionary.' His nephew and successor, Thomas Longman (1731-97), published a new edition of Chambers'. With Thomas Norton Longman (1771-1842) the firm reached a high degree of literary and commercial prosperity. Lindley Murray's 'Grammar' was published and proved valuable, while the firm had literary connection with Wordsworth, Southey, Coleridge, Scott, Moore (to whom it paid £3,000 for 'Lalla Rookh'), Sidney Smith, and other leading authors. In 1826 the 'Edinburgh Review' became the property of Longmans. The next important members of the firm were Thomas Longman (1804-79), the eldest son of T. N. Longman who issued a beautifully illustrated New Testament, and William Longman (1813-77), the third son, who wrote 'Lectures on the History of England' (1859); 'History of the Life and Times of Edward III.' (1869); and 'History of the Three Cathedrals of St Paul' (1873). The events of this generation were the publication in succession of Macaulay's 'Lays of Ancient Rome' (1842); 'Essays' (1843); and 'History.' The famous check for £20,000 paid to Macaulay as his share of the profits of the 3d and 4th volumes for the first few months (1855) is still preserved. The partners of the fifth generation were Thomas Norton Longman and George Henry Longman, sons of Thomas Longman, and Charles James Longman and H. H. Longman, sons of William Longman. One of the earliest ventures of this time was Disraeli's 'Endymion,' for which the author received £10,000. Lord Beaconsfield's other works had come into possession of the firm in 1870, when they published his 'Lothair.' A magazine—'Longman's'—was also established by the house.

Longobardi, lön-gō-bär'dī. See LOMBARDS.

Long's Peak, one of the highest elevations of the Rocky Mountains, in Colorado, about 48 miles northwest of Denver. Its height is 14,271 feet. It was named in honor of Col. Stephen Harriman Long (q.v.).

Long'spurs, a group of large finches, typically of the genus *Calcarius*, distinguished by the great size of the claw of the hind toe. All are northern birds, frequenting open lands and inclined to form into flocks. The Lapland longspur (*C. lapponicus*) is known throughout the northern parts of Europe and Asia as well as America, and breeds only in the extreme north, coming south of the area of deep snow in winter, but always rare and irregular in the United States. Three other species are restricted to

LONGSTREET—LONGUEVILLE

North America, one of which, the chestnut-collared (*L. ornatus*) is well-known in the West, as it breeds abundantly on the plains of Dakota and Montana, making its nest on the ground. All are handsome birds, with a mixture of colors, in which black, chestnut, red and buff are conspicuous. Detailed descriptions of all may be found in Dr. Coues' 'Birds of the Northwest' (1874).

Longstreet, Augustus Baldwin, son of William Longstreet (q.v.), American jurist and author: b. Augusta, Ga., 22 Sept. 1790; d. Oxford, Miss., 9 Sept. 1870. He was graduated at Yale College in 1813, began the study of law at Litchfield, Conn., and was admitted to practice in Georgia in 1815. In 1821 he represented the county of Greene in the legislature, and in 1822 was made judge of the superior court of Ocmulgee circuit. Declining re-election to the bench, he returned to the bar, and was especially distinguished for his efforts and successes in criminal cases. In 1822 he removed to Augusta, Ga., and founded the 'Sentinel.' In 1838 he entered the ministry of the Methodist church, and was president of Emory College 1839-48 and subsequently of the University of Mississippi. His works include: 'Georgia Scenes,' a series of broadly humorous sketches, long popular (1840); 'Letters From Georgia to Massachusetts.'

Longstreet, James, American soldier: b. in Edgefield district, S. C., 8 Jan. 1821; d. Gainesville, Ga., 2 Jan. 1904. He was graduated at the United States Military Academy in 1842; entered the army as lieutenant of infantry and, after performing duty at various Western posts, served in the Mexican War, in which (at Chapultepec) he was badly wounded and for gallantry in which he received the brevets of captain and major. From 1847 to 1852 he was stationed on the Texas frontier and in 1858 became paymaster with the rank of major. In June 1861, the Civil War having broken out, he resigned from the United States army and entered that of the Confederacy as a brigadier-general. At the first battle of Bull Run (q.v.) he commanded a brigade, and in 1862 was made a major-general. In the retreat before McClellan, during the Peninsular campaign (q.v.) he was in command of Gen. J. E. Johnston's rear guard, and contributed greatly to the safe withdrawal of the main army to Richmond. In the Seven Days' Battles (q.v.) he fought with credit to himself and his division, whose losses were very heavy; and at the second battle of Bull Run (q.v.) he displayed promptness, energy, and generalship to which the Confederate victory was largely attributed. He commanded the right wing at Antietam, and at the battle of Fredericksburg (q.v.) had command of the left, repulsing the desperate assault of Burnside's army. After Fredericksburg he was made lieutenant-general, and with that rank commanded one of the three corps of the Confederate army of invasion, known as the Army of Northern Virginia. At the battle of Gettysburg (q.v.) during the second and third days, he commanded the right wing, which sustained the chief burden of the conflict, furnishing the columns that made Pickett's charge. Transferred to the Army of Tennessee, Longstreet arrived on the field in time to save the day at the battle of Chickamauga (q.v.). He next

moved unsuccessfully against Burnside at Knoxville (q.v.) and early in 1864 rejoined General Lee in Virginia. Again distinguishing himself in the battles of the Wilderness, he was severely wounded and for some months disabled, but was in command of the First corps of the Army of Northern Virginia during the later months of 1864 and took some further part in active field-service, retaining to the last his distinction as a general and a fighter, and coming out of the war at its close with the respect of the whole country, which has never diminished. After the war he engaged in business in New Orleans and, having become a Republican in politics, was surveyor of customs at that port, 1869-73. In the same city he was afterward postmaster. He removed to Georgia in 1875; was United States minister to Turkey, 1880-1; in 1881-4 served as United States marshal of Georgia, and was appointed United States railway commissioner in 1898. He has written for periodicals, and has published 'From Manassas to Appomattox' (1896).

Longstreet, William, American inventor: b. New Jersey 1760; d. Georgia 1814. He settled in Augusta, Ga., in early life and on 26 Sept. 1790 wrote a letter to Thomas Telfair of Savannah asking his assistance in raising the means to construct a boat to be propelled by steam. This letter was published in the Savannah and Augusta newspapers, but funds were not immediately obtained, though he stated his entire confidence in the success of the scheme. He was subsequently furnished with the necessary means for experiment, and constructed a small model boat, upon a plan very different from Fulton's, which went on the Savannah River against the stream at the rate of five miles an hour. Cotton had previously been ginned by two rollers, not quite one inch in diameter, which caught the fibres, pressed out the seed, and delivered the clean cotton on the other side, where it was taken by the ginner's hand, and deposited in a bag attached to his person. Longstreet invented and patented the "breast roller," moved by horse power, which entirely superseded the old method. The inventor set up two of his gins in Augusta, which were propelled by steam, worked admirably, and promised him a fortune. They were, however, destroyed by fire within a week. He next erected a set of steam mills near St. Mary's, Ga., which were destroyed by the British in an invasion in the War of 1812. These disasters exhausted his resources and discouraged his enterprise, though he was confident that steam would soon supersede all other motive powers.

Longueuil, lōñ-gēl, Canada, town, in Chambly County, in the province of Quebec; on the Saint Lawrence River, and on the Canadian Pacific railroad. It is situated opposite Hochelaga, the northeastern part of Montreal. Longueuil is a residential suburb of Montreal, the country around contains many summer homes of city residents. It has Saint Anthony's orphanage and an academy for girls and one for boys. Pop. (1901) 2,835.

Longueville, Anne Geneviève de Bourbon Condé, än zhēn-vē-ēv dē boor-bōn kōn-dā lōng-vēl, DUCHESS OF, French beauty and politician: b. Vincennes 29 Aug. 1619; d. Paris 15 April 1679. Her father, Henry II., prince of Condé, was prisoner in the chateau of Vincennes

LONGUS — LOOM

at the time of her birth. Her brothers were the great Condé and the Prince of Conti. The Prince de Joinville, to whom she had been betrothed, having died, she married in 1642 the Duke de Longueville, a widower double her age. Imbibing a fondness for politics, she displayed it most actively in the part which she took in the Fronde. In order to punish the duchess, her brothers and husband were arrested by order of Anne of Austria, the regent, in 1650; but she persisted in her resistance to the court, and repaired to the citadel of Stenay in Flanders, of which she took the command, and was able to induce Turenne to join the Fronde. After the peace of 1659 she devoted herself to a religious life and her influence in Rome was said to have secured for the Jansenists the so-called peace of Clement IX. (1668). The later part of her life was spent in the Carmelite convent of Paris in most stringent observance of religious duties. Cousin, in his 'Madame de Longueville' (6th ed., 1859), calls her "the soul of the Fronde."

Longus, lōng'gūs, Greek writer, supposed to have lived about the close of the 4th or the beginning of the 5th century A.D. Concerning his history nothing is known. He was the author of a pastoral romance entitled 'The Pastorals of Daphnis and Chloe,' of which the best editions are those of Villoison (1778), Courier (1810), Passow (1811). Longus is the latest of the bucolic poets and in the Renaissance period was widely read, his pastoral descriptions, as given in Amyot's French translation, having not a little to do with the revival of the pastoral form.

Longview, Texas, town, county-seat of Gregg County; on the Texas & P., the Texas, S. V. & N., and the Great N. R.R.'s; about 240 miles northeast of Austin and 120 miles east of Dallas. It is situated in an agricultural section, in which are raised large crops of grain and cotton. The chief manufacturing establishments are foundry, lumber-mills, railroad-shops, cottonseed-oil mills, and plow-works. The principal offices of the Texas, Sabine Valley & Northwestern railroad are in Longview. The trade is principally in agricultural products, live stock, hides, cottonseed-oil, and lumber. Pop. (1890) 2,034; (1900) 3,591.

Long'worth, Nicholas, American wine manufacturer and horticulturist: b. Newark, N.J., 16 Jan. 1782; d. 1863. At 21 he went to the then unimportant settlement of Cincinnati, where he studied law. After 25 years' experience at the bar he retired from professional life in order to devote himself to the cultivation of the grape, with a view of manufacturing wine. At first his efforts were unsuccessful from his having adopted the erroneous notion of the early American vine growers, that foreign plants were alone to be relied upon. He had imported many different species from every vine-growing country in Europe before trying those indigenous to the United States. About 1828 he commenced the experiment, and became a high authority in vine culture, being not infrequently called the "Father of American Grape Culture."

Lönnrot, lén'röt, Elias, Finnish philologist: b. Sammatti, in Nyland, 9 April 1802; d. there 19 March 1884. Recognizing the value of the people's songs and ballads for Finnish language

study, he spent years in collecting such material in Finland, Lapland, and adjoining provinces, and published the fruits of his researches in a series of volumes. Among his "finds" is to be numbered the great popular epic 'Kalevala,' of which only a few cantos were previously known to the learned world. He wrote a 'Finnish-Swedish Dictionary' (1866-80). See KALEVALA.

Loo (short for lanterloo, from the Dutch name), a game of cards played with five (sometimes three) cards, dealt from a whole pack, either by threes and twos, or one at a time. After dealing, a card is turned up for trumps. The jack of clubs, or the jack of the trump suit, as agreed on, is the highest card, styled "pam"; the ace of trumps is next, and then the other cards as in whist. Five cards of a suit, or four with "pam," compose a "flush," which sweeps the board, and yields only to a superior flush, or the elder hand. When the ace of trumps is led, it is usual to say, "Pam be civil"; the holder of the jack (of trumps or clubs; see above) is then expected to let the ace pass. Each player has the liberty of changing his cards for others from the pack, or of throwing up the hand, in order to escape being looed, that is, failure to gain a trick. All those that win tricks divide the pool or "loo," to which on entering the game each player contributes chips (usually three) in proportion to the tricks taken. Every player who is looed must again contribute a stake, which, with the dealer's stake, forms a new pool.

Loo'-choo Islands. See LIU-KIU ISLANDS.

Loo'fah, Egyptian, the fibrous portion of the fruit of one or two species of the genus *Luffa* of the gourd family, sold for use as a bath-sponge or flesh-rubber. There are about 10 species of the genus known, but the "towel gourd," as this bath-sponge is sometimes called, appears to be obtained chiefly from *L. aegyptiaca*. In the West Indies the fruit of *L. acutangula* yields a similar network of fibres, and is there used as a sponge or dishcloth, and worked up into baskets and small ornamental articles.

Looking Backward, 2000-1887, a romance by Edward Bellamy, published in 1888. It had a sale of nearly 400,000 copies in the next ten years, and is still in demand. It recounts the strange experiences of Julian West, born in 1857, who in 1887 is put into a hypnotic sleep. In the year 2000, Dr. Leete, a retired physician, is conducting excavations in his garden, when West's subterranean chamber is disclosed. The doctor discovers and resuscitates the young man, who finds himself in a regenerated world.

Lookout Mountain. See CHATTANOOGA, BATTLE OF.

Loom, a term originally meaning simply "tool," but now particularized so as to apply to a machine for weaving. The simplest form of the loom, still in use among semi-primitive tribes and up to the middle of the 18th century practically the only form, was the hand loom, a rectangular frame,

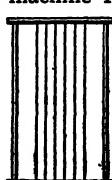

FIG. I.

frame, from one side of which yarn is stretched to the opposite side, where it is so secured that the transverse threads may be passed by hand "over and under" the threads already stretched. Fig. I

LOOMIS

shows the simplest form of this loom. The form in commoner use in civilization up to Cartwright's invention of the power loom in 1785 is merely this same actual frame set in a skeleton box (AAAA) in a horizontal position (Fig. 2). The end pieces of the actual frame are now rollers, so that the length of the piece of cloth is no longer necessarily less than the length of the frame. These rollers are the beam or yarn-roll (B), which is at the back of the loom, and upon which the warp threads are wound, and the cloth beam (C) to which the threads are fastened and which winds up the cloth as it is made. The threads of the warp, held tight by weights (b, b), pass through the eyes of the heddles (or healds), thus being separated to permit of the passage of the shuttle, and also through the reed. The shuttle in the hand-loom is thrown by the operator, and in the power loom by the picker-staff machinery; in either case it is made of hard wood, is pointed at either end and carries in a recess the quill or bobbin.

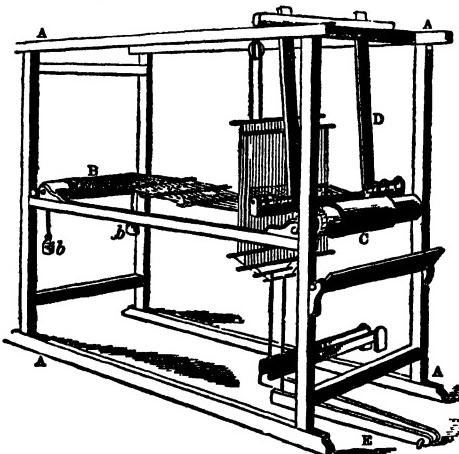

FIG. 2.

This hand-loom was first successfully improved, after the unfortunate attempts of De Gennes in 1678, by Edmund Cartwright, who undertook in 1785 to counterfeit by mechanical means the three simple motions of weaving. He had neither mechanical nor textile training, but his loom though cumbersome and awkward is essentially that now in use. The simplest modern loom differs essentially from the hand loom in that the warp yarn is no longer stretched direct from the yarn roll to the cloth beam, and these two parts are no longer placed at the same height from the base of the frame nor at so great a distance as before. The yarn runs upward from the warp-beam over the whip-roll, thence is carried through heald, heddle, or (the American term) harness, and through the reed, and down from the latter to the cloth roll. The advantage of this arrangement is greater stability and a distinct saving in space, the depth of the loom being materially decreased. With the old fashioned heddle only the simplest and most regular webs could be woven; for figured patterns the most effective mechanism is the Jacquard attachment, patented by a weaver of Lyons, Joseph Marie Jacquard, in 1801. This machine lends itself readily to use with any loom. It may be described as a means of forming the

shed and governing the heddle,—in fine, it takes the place of the weaver's fingers. A revolving drum or cylinder is so perforated as to catch some or all needles, which in turn govern a set of perpendicular hooks. These hooks guide the threads of the warp, so that the weaving is no longer of necessity simply "under or over." How many threads are to be skipped is determined by a perforated card-board, the perforations occurring where the thread of the warp is to lie above the filling; but if the warp-threads are not to be raised no holes are cut in the cards, the needles do not enter the cylinder, and the hook attached to the needle does not lift, by means of its neck-cord or loop of twine, the thread of the warp. A series of these cards, each with different perforations, makes an almost infinite combination of patterns possible, as each card makes a different shed.

The hand loom is still used for the manufacture of rugs and fine carpets, but the power loom, driven by various powers, electricity being the latest and in some ways the most economical, is used for almost any purpose. The ribbon-loom, for instance, weaves simultaneously a number of narrow pieces. Many attachments, invented in a long series, have continuously and wonderfully decreased the need of any supervision of the loom, making it more and more automatic: thus a shuttle protector automatically stops the machinery if the shuttle fails to fly all the way across the warp; the filling stop motion protects the machinery from running on uselessly when the filling breaks or runs out; and take-up, let-off, and warp-stop motions are further automatic devices. The highest pitch of automatic attachment is the Northrop patent, which is a hopper full of loaded bobbins; these are fed into the place of the empty bobbins as soon as the yarn is exhausted.

See Posselt, 'Textile Machinery' (1901) and 'Jacquard Machine Analyzed and Explained' (1893); and Barlow, 'History and Principles of Weaving by Hand and by Power' (1879).

Loomis, Alfred Lebbeus, American physician: b. Bennington, Vt., in 1833; d. 23 Jan. 1895. He was graduated at Union College in 1851, and studied medicine in New York city at the College of Physicians and Surgeons, where he was graduated in 1852. He gave his attention to diseases of the lungs at a time when auscultation and percussion were acquiring great scientific importance in medical practice, and in the treatment of such diseases became an efficient specialist. In 1859 he was appointed visiting physician to Bellevue Hospital, New York, and was made lecturer on physical diagnosis at the College of Physicians and Surgeons in 1862. Having spent some months in the Adirondack Mountains for the improvement of his health, in later years he established the Sanitarium at Saranac and the Hospital for Consumptives at Liberty, N. Y. In 1866 he accepted the professorship of theory and practice of medicine at the University of the City of New York, remaining in connection with that institution until his death. The work done by him for its medical department was of great and lasting importance, as were also the services he rendered to the New York Academy of Medicine. In 1874 he was appointed visiting physician to Mount Sinai Hospital: was president of the New York Academy of Medicine, 1899-90 and 1901-2. His publications include 'Lessons in Physical Diag-

LOOMIS—LOOSESTRIFE

nosis' (1870); 'Lectures on Fevers' (1877); and 'A Text-book of Practical Medicine' (1884). He also edited 'An American System of Medicine' (1894).

Loomis, Charles Battell, American humorist: b. Brooklyn, N. Y., 16 Sept. 1861. He was educated at the Brooklyn Polytechnic Institute and held a business clerkship 1879-91. He is a frequent contributor to periodicals and has published 'Just Rhymes' (1890); 'The Four-Masted Cat-boat' (1890); 'Yankee Enchantments' (1900); 'A Partnership in 'Magic' (1903).

Loomis, Chester, American painter: b. near Syracuse, N. Y., 18 Oct. 1852. He was educated at Cornell University (1868-71); studied painting at Paris under Léon Bonnat, and after a residence of 11 years in France opened a studio at Englewood, N. J. He is favorably known as a figure and landscape painter and his pictures are found in many private collections. His 'Christopher Sly' was awarded a gold medal at the Massachusetts Charitable and Mechanics' Institution Exhibition and was subsequently purchased by the Indianapolis Art Association.

Loomis, Elias, American physicist: b. Willington, Conn., 7 Aug. 1811; d. New Haven, Conn., 15 Aug. 1899. He was graduated at Yale College in 1830, and was tutor there in 1833-6. He was the first person in America to obtain a view of Halley's comet, at its return in August 1835, and his observations on that body, with a computation of its orbit, were published in the 'American Journal of Science.' After a year's study in Paris he was professor (1837-44) of mathematics in Western Reserve College, Ohio, of natural philosophy (1844-60) in the University of New York, and of natural philosophy and astronomy (from 1860) at Yale. He devoted much of his time to original research, wrote more than 100 scientific treatises, and published a series of text-books on mathematics, natural philosophy, astronomy, and meteorology, of which more than 500,000 copies were sold. Among his publications were: 'Elements of Algebra'; 'Elements of Geometry and Conic Sections'; 'Recent Progress in Astronomy.'

Loomis, Francis B., American journalist and diplomatist: b. Marietta, Ohio, 27 July 1861. He was a graduate from Marietta College, and in 1883 joined the staff of the New York *Tribune*. He was state librarian of Ohio 1885-7; consul at St. Etienne, France, 1890-3, and editor-in-chief of the Cincinnati *Daily Tribune* 1893-6. He was United States envoy-extraordinary and minister plenipotentiary to Venezuela, 1897-1901, and while there was active in promoting the interests of American commerce in South America. He filled the same diplomatic position at the court of Portugal 1901-03, and became assistant secretary of state in January 1903.

Loomis, Gustavus, American soldier: b. Thetford, Vt., 1789; d. 1872. He was graduated at West Point and received his commission as sub-lieutenant of artillery in 1811. He saw service on the Niagara frontier from 1812 to 1813, in which latter year he took part in the capture of Fort George (May 27) and was made prisoner the following December at Fort Niagara. During the war with Great Britain, the Black Hawk war, and the campaign against

the Seminole Indians, he held important commands, and after the Civil War, in which he served as superintendent of the general recruiting service, was retired with rank as colonel of infantry. In 1865 he received the brevet of brigadier-general of the United States army.

Loomis, Lafayette Charles, American author and educator: b. North Coventry, Conn., 7 July 1824. He was graduated from Wesleyan University, Conn., in 1844, and was successively president of colleges at Wilmington, Del., and Wheeling, W. Va., and later medical professor at Howard University, Washington, D. C. He has published 'Mizpah' (1859); 'Mental and Social Culture' (1868); 'Index Guide to Travel and Art Culture in Europe' (1880); 'Myself' (1894).

Loomis, Silas Lawrence, American scientist and inventor: b. Coventry, Conn., 1822. He was graduated from Wesleyan University in 1844, from the medical school of Georgetown University in 1856, and was professor of physiology at Georgetown in 1859-60. In 1857 he was appointed astronomer to the United States coast survey, in 1860 instructor in mathematics to naval cadets, in 1861-7 was professor of chemistry and toxicology at Georgetown, and subsequently occupied a chair at Harvard. Among his inventions are a process for manufacturing a textile fabric from the palmetto, and another for making profitable use of chromium ores. He wrote text-books of arithmetic, a 'Key to the Normal Course' (1867), and other works.

Loon, lō-ōn', Philippines, a pueblo of the province of Bohol, situated on the west coast, 13 miles north of Tagbilaran, and opposite Dala-guete, Cebu. A mole 328 yards long, protecting the harbor, extends to the town, which is reached by steps cut in the rock. It is picturesquely situated on the slope of the Cammanoc hills, and has an old Spanish fort with bastions. It is centrally located for trade, and is the largest town in the province. Pop. 15,400.

Loon. See DIVER.

Loos, 16s, Charles Louis, American educator: b. Woerth-sur-Sauer, Basse-Alsace, France, 23 Dec. 1823. He came to the United States in 1832, and settled at New Franklin, Ohio, where he studied English, became connected with the Disciples of Christ in 1858 and preached at 17. He was graduated from Bethany College in 1846, where he was professor of ancient languages 1858-80. He was president of Kentucky University 1880-97. In 1849 he was ordained to the ministry of the Disciples and has been of great prominence in his denomination.

Loosestrife, a plant of the genus *Lysimachia*, of the primrose family, about 40 species of which grow in the temperate zone. Several yellow-flowered species belong to the United States, but those best known are the whorled or four-leaved (*L. quadrifolia*), and the bulb-bearing, *L. terrestris*. Two or three species, especially *L. nummularia*, popularly known as moneywort, creeping Charley and creeping Jenny, have been introduced from Europe. One kind is eaten in India as a pot-herb with fish. "Again and again," says Miss Lounsbury, in her 'Southern Wild Flowers and Trees,' "we come across the loosestrifes during our summer and early autumn rambles. And soon we learn to associate with them their opposite, or

LOPE DE VEGA—LOPEZ

whorled, leaves, always entire, and their upright, rather stiff manner of growth, and very frequently we look for their petals to be darkly spotted near the bases. In personality the genus reminds us somewhat of the St. John's-wort, but we think of the latter as being usually freer, more prolific bloomers. The old and pretty legend concerning our present plants is that they loose strife; that they act as peace-makers especially among cattle that are quarrelsome. Believing this, people in the old country used to tie such a spray to their yokes before starting out on a long journey."

The name loosestrife is also given to species of the genus *Lythrum*, which some botanists place in the order *Primulaceæ*, of which about a dozen species are widely distributed in temperate climates. They are characterized by four-angled stems, usually opposite leaves which are sometimes whorled, and reddish-purple or white flowers, solitary above and whorled lower down the stems. Some are cultivated for ornament in borders and among shrubbery, where they succeed well. The best-known species is the purple loosestrife (*L. salicaria*), which is frequently planted.

Lope de Vega, lō pā dā vā'gā. See VEGA, CARPIO.

Lopes, lō'pāsh, Caetano, Brazilian historian: b. Bahia October 1780; d. Paris 22 Dec. 1860. He was a mulatto and after obtaining an education in Bahia and Paris, France, settled in the latter place in 1822 and became corresponding member of the Academy of Inscriptions and Belles-lettres. The Emperor Pedro held him in high esteem and the Historical Institute of Rio Janeiro bestowed him its gold medal. He was conspicuous for brightness of style and purity of language. His works, which are numerous, treat of history, biography, and surgery.

Lopes, or Lopez, Fernao, Portuguese chronicler: b. about 1380; d. after 1459. He was appointed chief archivist of the kingdom by Dom Joao I. in 1434, and spent his life in historical research and the composition of chronicles, which for literary and critical value were unsurpassed in his century. His 'Chronicle of Señor Don John I.' describing the great struggle between Portugal and Castile, invites comparison with Froissart's chronicle on account of its picturesqueness and dramatic reality. Equally vigorous are his chronicles of Dom Pedro I. and Don Fernando.

Lopez, lō'pāz or lō'pāth, Carlos Antonio, President of Paraguay: b. near Asuncion about 1795; d. there 19 Sept. 1862. He was educated in Asuncion and became noted for his legal acquirements. After the death of President Francia, in 1840, he was secretary of the junta which controlled Paraguay for a few years. In March 1844 the Paraguay congress adopted the constitution he had drawn up and elected him president of Paraguay for ten years. He was re-elected for three years in 1851; and again in 1857 for seven. He followed Francia's policy in the main and became involved in quarrels with foreign nations. In 1859 the United States sent a naval force to the Plata to enforce demands against him. He offered to submit the question of damages to arbitration, but afterward evaded the claim.

Lopez, Francisco Solano, Paraguayan president: b. Asuncion 24 July 1827; d. near the Aquidaban 1 March 1870. He was the son of Carlos Antonio Lopez (q.v.), then president. In his 18th year his father made him a brigadier-general in the war against Rosas, the dictator of Buenos Ayres. He afterward filled some of the principal offices of state, and was sent to Europe in 1853, accredited to the chief courts there. In 1855 he returned to Paraguay, became minister of war, and on the death of his father, in 1862, president for ten years. He had aimed at the foundation of a great inland empire, and as his military preparations were now complete, and his army superior to that of any of the South American states, he began hostilities against Brazil in 1864. The Argentine Republic and Uruguay allied themselves with Brazil, and after five years' conflict Lopez was reduced to extremities, and was finally surprised on the banks of the Aquidaban by a troop of Brazilian cavalry and slain. The latter part of his career had been stained by many cruelties and wanton murders. Consult: Thompson, 'The War in Paraguay' (1869); Masterman, 'Seven Eventful Years in Paraguay' (1869); Burton, 'Letters from the Battle Fields of Paraguay' (1871); Washburn, 'History of Paraguay' (1871); Schneider, 'Der Krieg der Triple-Allianz' (1872-5).

Lopez, José Hilario, hō-sā' hē-lā'rē-ō, Colombian politician: b. Popayan 18 Feb. 1798; d. Neiva 27 Nov. 1869. He was president of New Granada (Colombia) from 7 March 1849 to 7 March 1852, and in the last named year slavery was abolished and changes were made looking to the formation of a federal government. In the revolutions of 1854 and 1859-62, he fought with the Federalists and was commander-in-chief for part of this period. He was a member of the provisional government 1862-3, and subsequently President of Tolima. In 1867 he was named commander-in-chief of the army. *

Lopez, Narciso, Cuban revolutionist: b. Venezuela 1799; d. Havana, Cuba, 1 Sept. 1851. He served for some time in the Spanish army, from which he retired in 1822 with the rank of colonel. After the evacuation of Venezuela by the Spanish troops, he established himself in Cuba, and afterward during a stay at Madrid joined the party of Isabella against Don Carlos, and became successively adjutant of Valdes, governor of the Spanish capital, and senator for Seville, but threw up his offices after the refusal of the Cortes to admit the representatives of Cuba. Valdes became governor-general of that island, and Lopez on returning thither was employed by him in various capacities. He was soon absorbed by the project of throwing off the yoke of Spain, and he proceeded in 1849 to the United States, where he sunk almost his whole fortune in the organization of three successive expeditions to Cuba: the so-called Round island expedition in 1849; the "invasion of Cardenas" expedition in May 1850, both of which failed, and the Bahia-Honda expedition, of August 1851, which ended fatally. Lopez, with several hundred persons of different nationalities whom he had enlisted in various parts of the United States, landed at Morillo, near Havana, where he left 200 of his men under the command of Colonel Crittenden, who were taken by the

LOPEZ — LORCA

Spaniards and shot. Lopez went to Las Pozas, where he succeeded in repelling an attack of the Spanish soldiers; but, isolated from his friends, sought refuge in the mountains, where he was captured and taken to Havana. He was sentenced to death, which he met with great firmness.

Lopez, Vicente Fidel, Argentine historian: b. Buenos Ayres 1814. He is a son of Vicente Lopez y Planes (q.v.). He became rector of the University of Buenos Ayres and has published 'Razas del Perú anteriores a la Conquista'; 'Historia de la República Argentina'; 'Tratado de Derecho Romano'; etc.

Lopez, Cape. See CAPE LOPEZ.

Lopez de Ayala, Pedro, pā'drō, Spanish ardo, Spanish dramatist: b. Seville district 1 May 1828; d. Madrid 30 Jan. 1879. He was educated at the University of Seville, and at Madrid in 1851 had his first drama, 'El Hombre de Estado,' produced. In 1857 he was elected deputy from Badajoz to the Cortes, and subsequently he was a member of Alfonso XII's first cabinet. He was the author of numerous lyrics which take excellent rank in Spanish literature, especially of the 'Epistola.' But he was better known as a dramatist of high literary and popular success. Chief of his plays are 'Tanto por Ciento' (So Much per Cent), which was recognized by the bestowal upon him of a gold crown, and 'Consuelo.' Both are searching arraignments of the principles of modern life.

Lopez de Ayala, Pedro, pā'drō, Spanish poet: b. Murcia 1332; d. Calahorra 1407. He served well Henry II, John I., and Henry III., kings of Castile, attained the highest dignities, including those of lord chancellor and high chamberlain of Castile, and wrote the 'Cronicas de los Reyes de Castilla' ('Chronicles of the Kings of Castile') (1780), which covers the period from King Peter to Henry III. In this work he strove to substitute for the dry record of the historiographers a pragmatic account of historical events. He also wrote lyrics, and the 'Rimado de Palacio' ('Rime of the Palace'), a satiric poem on political and social questions.

Lopez y Planes, lō'páz or lō'páth ē plā'nés, Vicente, Argentine poet: b. Buenos Ayres 1814; d. there 1856. He was prominent as a soldier and politician, was member of Congress, 1819-25, and provisional president of the republic, 5 July to 13 Aug. 1827. He presided over the supreme court of justice, and was governor of the province of Buenos Ayres. He was the author of the 'Argentine National Hymn' and other poems.

Lophiodon, an extinct tapir-like animal, found in the Eocene fresh-water deposits of central Europe. The genus is typical of a family (*Lophiodontidae*) which includes also the genera *Hyracotherium*, *Hyracus*, *Systemodon* and *Orohippus*, and is a very generalized group probably ancestral to the rhinoceroses. Consult Woodward, 'Vertebrate Paleontology' (1898).

Lophobranchii, lō-fō-brang'ki-i, a suborder of bony fishes, including the "sea-horses" and "pipe-fishes" (*Syngnathidae*). See ICHTHYOLOGY.

Loquat lō'kwat, or Japan Plum, a shrub or small tree (*Eriobotrya japonica*) of the natural order Rosaceæ. It attains heights of about 20 feet, bears thick evergreen leaves near the

ends of the branches, and fragrant, woolly, whitish flowers in terminal panicles in late summer and autumn, followed by downy yellow oval or pyriform fruits (pomes) which ripen in very early spring. The fruits, which in favorable climates are borne in profusion, are highly esteemed for their sub-acid flesh and their pleasantly flavored seeds, the former being used as a dessert, the latter for flavoring cookery. The tree is a native of Japan and China, whence it has been taken to subtropical climates throughout the world. In the Gulf States and in California it is widely popular as a home fruit, though it appears in northern markets. In California several highly improved varieties were produced during the closing decade of the last century. In the north it is often grown in conservatories.

Lorain, lō-rān', Ohio, city, in Lorain County; on the south shore of Lake Erie, at the mouth of the Black River, and on the New York C. & St. L. (Nickel Plate), Baltimore & O., and Lake Erie & Pittsburg R.R.'s; about 26 miles west of Cleveland. The first permanent settlement was made in 1822 by Barney Meeker. It was incorporated as a village in 1873 and as a city in 1895. It is an agricultural and natural-gas region, and is a shipping port for farm products, for the output of the Central Ohio coal fields, and for the lumber and iron ore of a large section of the State. The chief industries of the city are ship-building, coal shipping, manufacturing steel, general manufacturing, and fishing. The Lorain Steel Company employ about 4,000 people; the American Shipbuilding Company, 1,300; the Baltimore & Ohio, in shops, at docks, etc., 1,000; small industries, about 2,000. The city has excellent public and parish schools, a public library, 22 churches, and Saint Joseph's Hospital. There are five banks with a combined capital of \$300,000. The annual amount of business is about \$2,500,000. About 75 per cent. of the inhabitants are American born. The government is vested in a mayor, a board of public service (three members), and a council of seven members. Four of the council are elected one from each ward, and the other three, at large. The board of education, waterworks trustees, and marshal are chosen by popular election; the board of health are chosen by the council; the police are appointed by the mayor subject to approval by the council. The waterworks are owned and operated by the city. Pop. (1890) 4,863; (1900) 16,028. F. A. ROWLEY,

Editor of 'Times Herald.'

Lorca, lōr'kā, Spain, city, in the province of Murcia; on the Sangonera River; about 20 miles north of Aguilas, the Mediterranean port. It is an ancient city, established before the Moors came to Spain, as is evidenced by the older houses; but the main part of the city now existing is of Moorish construction. It has considerable manufacturing interests, and in the vicinity are valuable mines of silver, sulphur, and lead. The farms in the surrounding country have to be irrigated in the dry seasons, and for the storage of water of the Sangonera a dam, 800 feet long and 160 feet high, was built near the city. In 1802 the dam burst, and the valley was flooded. Many lives and much property were lost. Lorca was the scene of many battles between the Christians and the Moors. Pop. 70,127.
